

Logic Neural Networks: Ultra-Fast ML for Triggers and Beyond

RAL seminar 2026

28.01.26

This presentation contains animations - best viewed in .pptx or .key

Lino Gerlach, Thore Gerlach, Elliott Kauffman, Liv Våge

Who I am

Teaching ML since 2017

Who I am not
An FPGA expert

PhD at Imperial College

New directions for particle tracking at the
High-Luminosity LHC

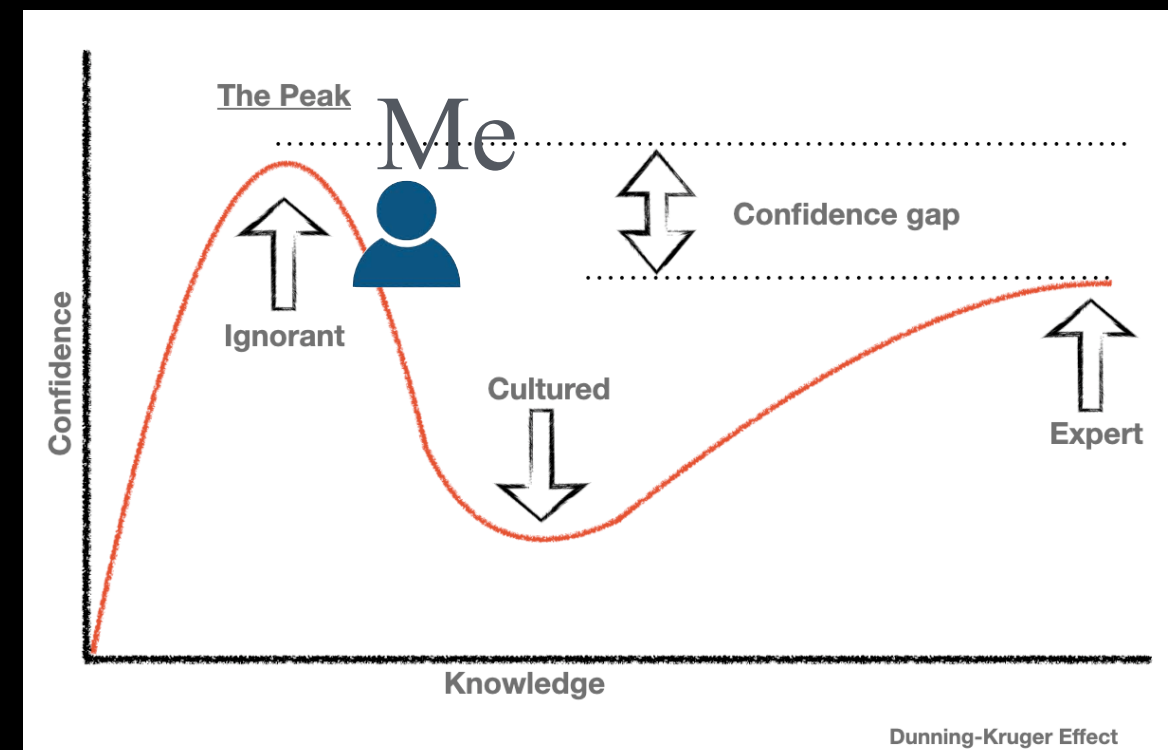

GNNs and reinforcement learning
for tracking

Working with IRIS-HEP,
based in Geneva

Innovative algorithms

GNNs for tracking
Rapid inference

ML infrastructures in HEP

Motivation

Low latency needs
Hardware solutions
Software solutions
Why we need more

Application to HEP

Application to CICADA anomaly detection
Strength and weaknesses
Future opportunities

Logic neural networks

Overview of the field
Differentiable logic gate neural networks
New developments

Conclusion

Summary
How to get started

Introduction

Low latency inference - evaluating ML fast

When we want ML that is:

Close to host

Edge computing is increasing:
now at ~ [21 billion IoT devices](#)

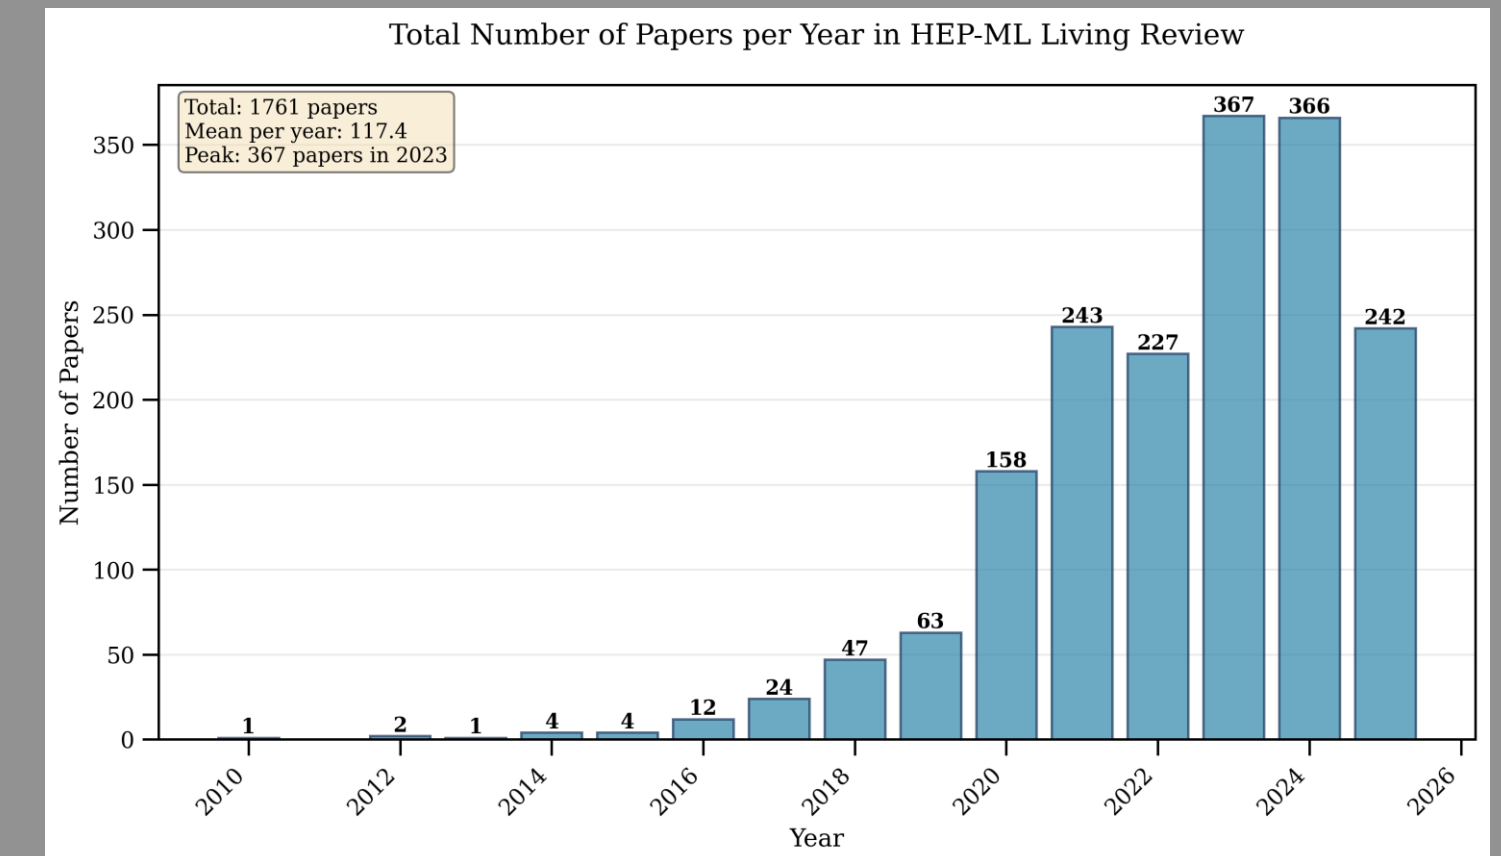

Cheap and efficient to run

LLMs, medical devices, space devices etc.
Pacemakers need ~ [50 microwatts to run for 7 years](#)

Super fast

Financial trading ([Spread networks e.g. spent 300 M on a cable to save 13 ms](#)), self driving cars and lots more

HEP

* This plot was made around October 2025

ML use

ML use is increasing in HEP. We have huge and increasing amounts of data

Triggers

The Phase 2 CMS Level 1 Trigger will for instance need to process 63 Tb/s with a latency of 12.5 μ s

How much of the energy consumption and cost does inference account for in an ML pipeline?

10-30%

0%

30-50%

0%

50-70%

0%

70-90%

0%

Inference devices

Lower latency and power, harder to program

With high luminosity LHC and FCC, we are moving towards the right to handle our data quickly

| | CPU | GPU | TPU/NPU | FPGA | ASIC |
|----------|-----------------------------|------------------------------|-------------|----------------------------|---------------------------------------|
| Latency | ms-s | μ s-ms | μ s-ms | ns- μ s | ns |
| Strength | Flexible easy to program | Parallelism, ML optimised | ML-specific | Deterministic Low power | Ultimate speed/power efficiency |
| Weakness | Slow, high power | High power | Bespoke | Hard to program | Expensive Not flexible |

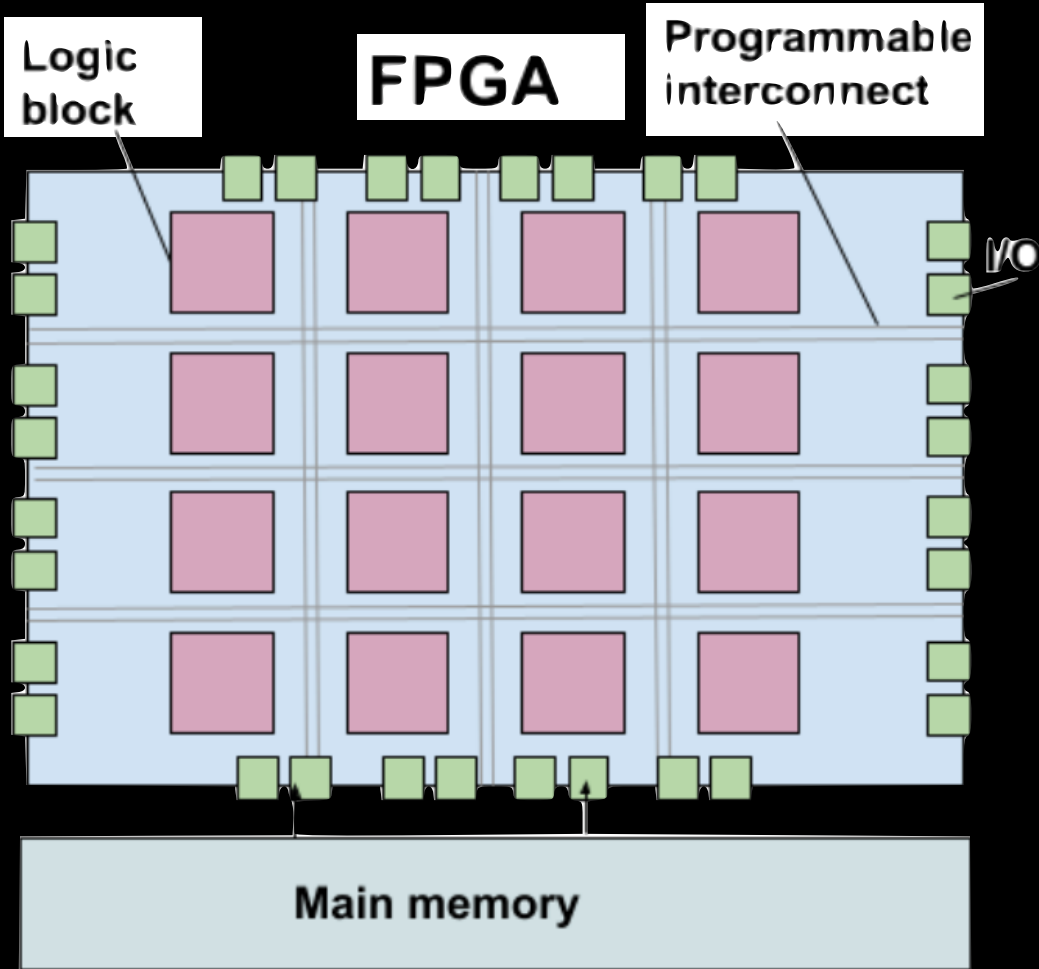

Small ML models
(e.g. BDTs)

Most ML

Low inference ML

No matter what chip we use or how we program it - it is ultimately translated to binary logic

Field Programmable Gate Arrays (FPGAs)

Hardware you can reprogram after manufacturing

Massively parallel → very fast for specific tasks

Deterministic timing (no caches, no surprises)

Programmed using Verilog / VHDL

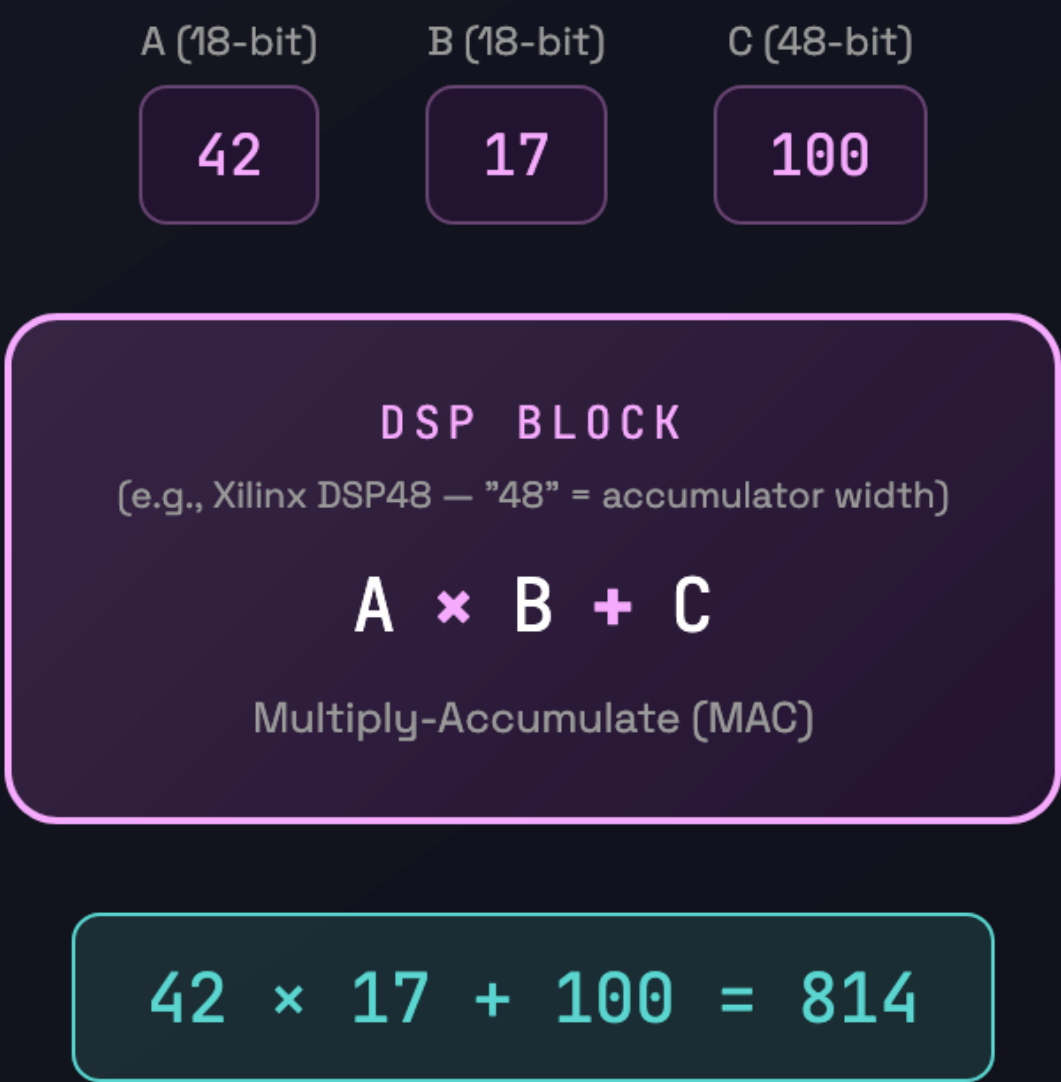

Can also use high-level tools (e.g. HLS, hls4ml)

Available in radiation-tolerant versions for space or HEP detectors

DSPs and LUTs

DSP — Digital Signal Processor

Hardwired arithmetic unit for fast math

⚡ Speed

1 cycle throughput (pipelined), ~3-4 cycle latency

🎯 Purpose

General arithmetic: multiply, add, accumulate, shifts, pattern detect

📦 Capacity

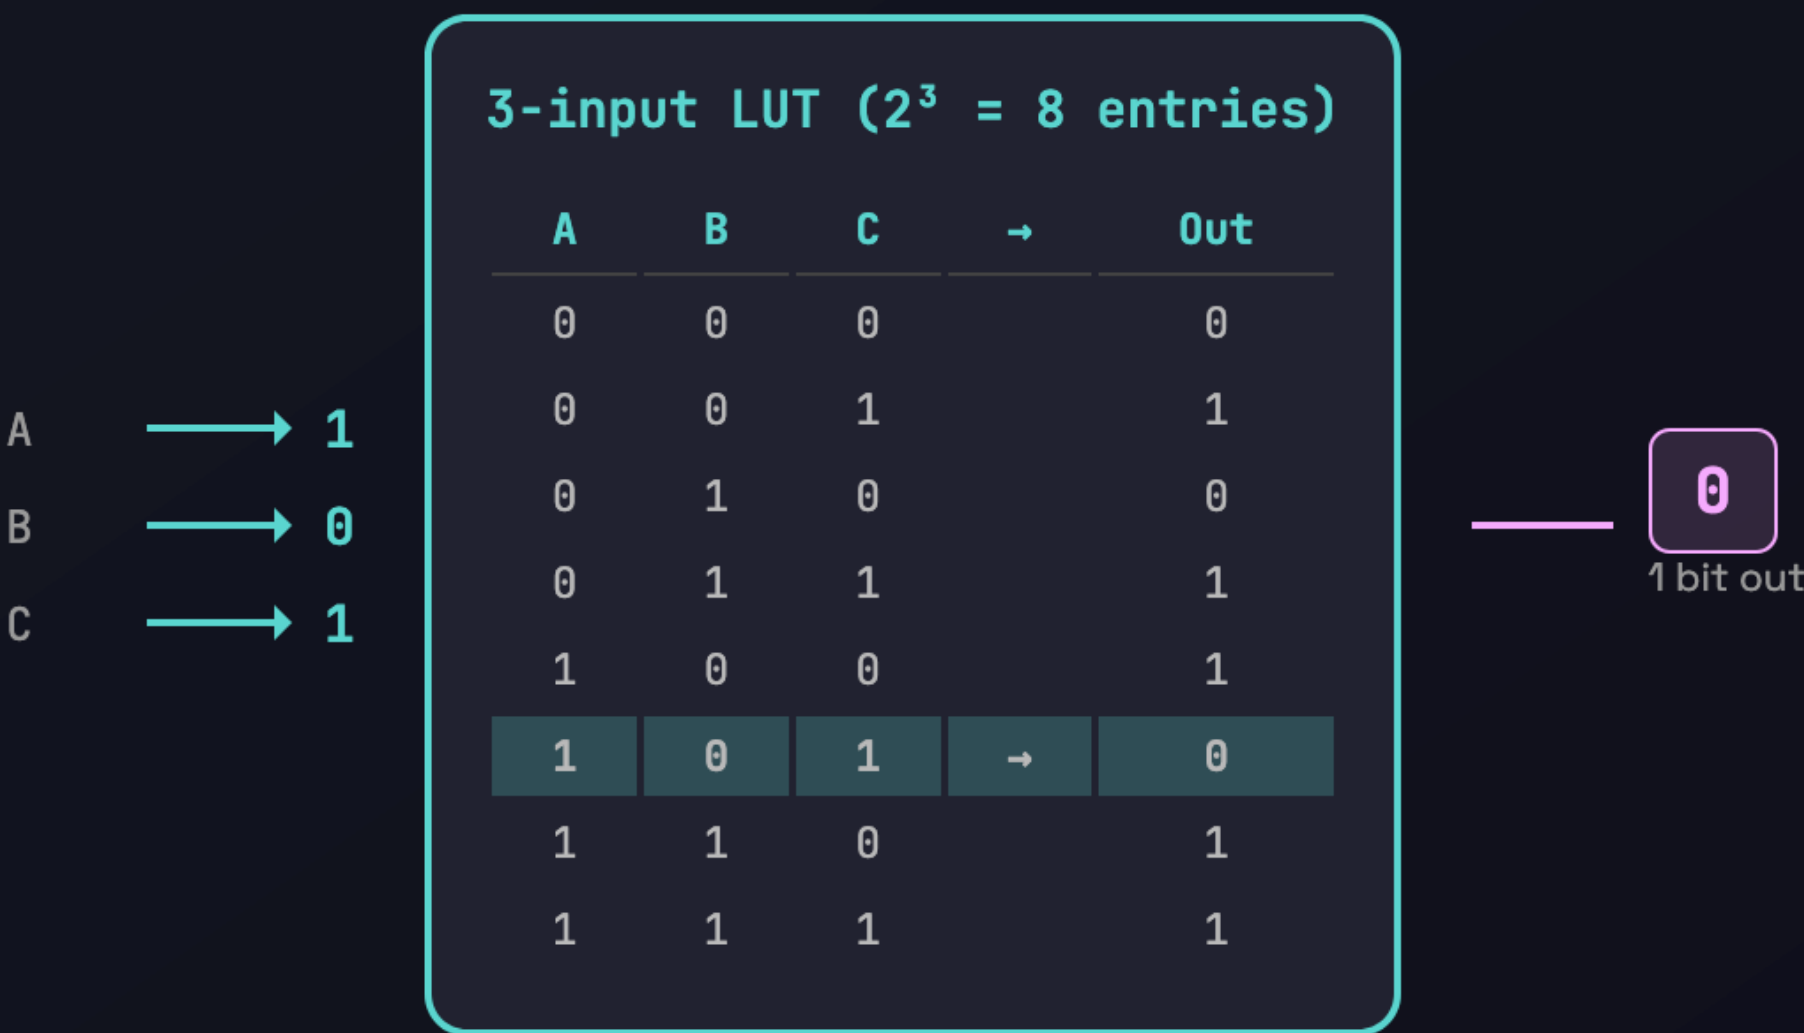

18×18 bit multiply → 48-bit result

📦 Key constraint

Limited count (~2-6k per FPGA) — they're big!

LUT — Lookup Table

A tiny programmable truth table that outputs 1 bit

⚡ Speed

Single clock cycle — just a memory read

🎯 Flexibility

Can implement ANY boolean function of N inputs

📦 Size

Modern FPGAs have 6-LUTs (64 entries each)

📦 Key constraint

Each LUT outputs only 1 bit — need multiple for wider outputs

Computing: $y = (3 \times x) + 1$ where x is a 4-bit input (0-15)

DSP Using a DSP Block

- 1 Configure DSP
 $A = 3, C = 1$ (constants)
- 2 Feed input each cycle
 $B = x$ (your 4-bit input)
- 3 DSP computes
 $y = A \times B + C = 3x + 1$

RESOURCES

1 DSP

(precious!)

LATENCY

1 cycle*

*or 3-4 if pipelined

LUT Using LUTs

- 1 Pre-compute ALL 16 answers
 $x=0 \rightarrow 1, x=1 \rightarrow 4, x=2 \rightarrow 7, \dots x=15 \rightarrow 46$
- 2 Store each output BIT in a separate LUT
Output range 1-46 needs 6 bits
- 3 Look up using x as address
 $y = \{LUT_5[x], LUT_4[x], \dots, LUT_0[x]\}$

6 LUTs working in parallel (one per output bit)

RESOURCES

6 LUTs

(abundant!)

LATENCY

1 cycle

(always)

Current fast inference methods

Pruning

Remove unnecessary weights & neurons

Can often reduce the number of parameters by 3-10x

Often you get better performing retraining the pruned network

Quantisation

Reduce numerical precision

Makes it better for FPGA

Accuracies suffer below int4

Knowledge distillation

Small model learns behaviour of a large one

Used for anomaly detection in CMS

You have to start with a large model and the tuning can be hard

Scaling wall

All these approaches aim to learn something big and then reduce - maybe we could learn small from the start

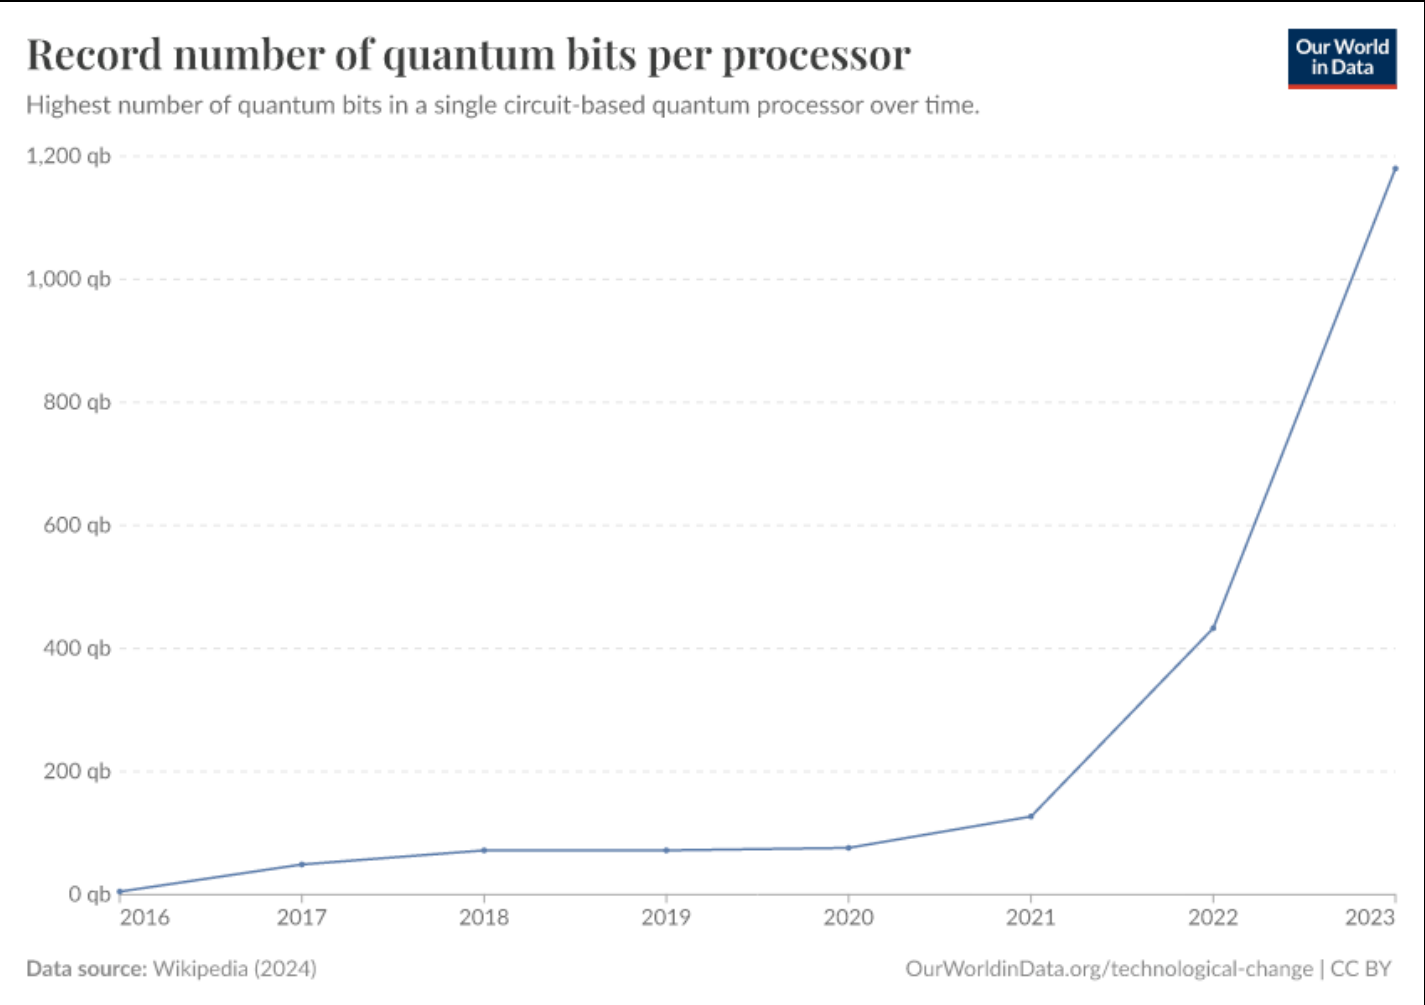

Could we learn ML suited directly for our hardware?

There are a few paradigm shifting potentials

Neuromorphic computing

Quantum computing

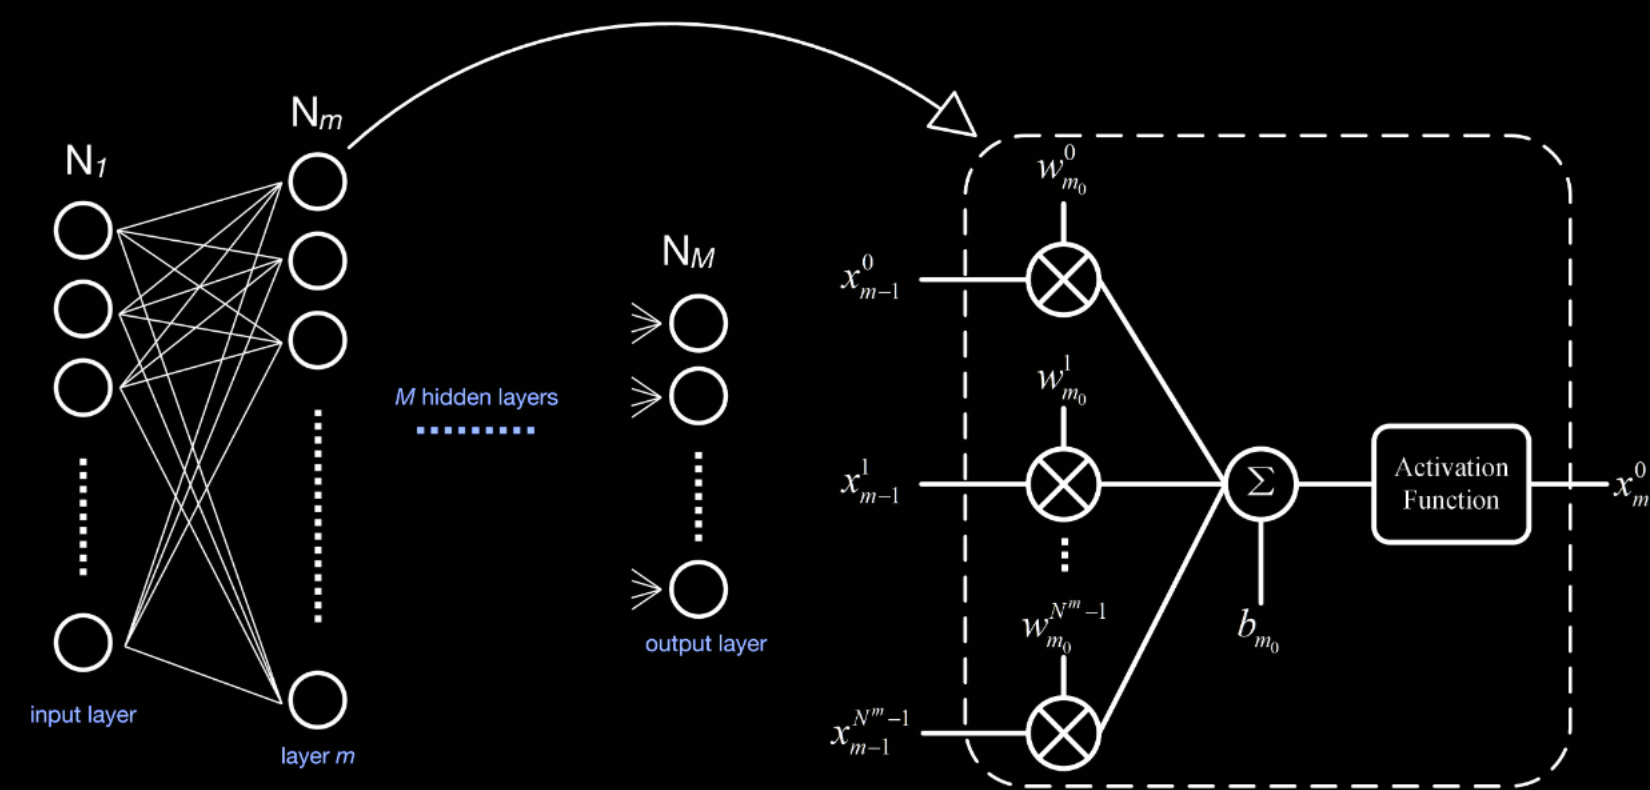

Abstracts from NeurIPS and ICML that mention keywords related to scaling or inference

Fast inference needs are increasing

We are moving to more specialised hardware

Our techniques for making ML fast are not enough

Logic neural networks

Evolution of the field

1959

Weightless learning

Ntuple

Early character recognition by storing states in RAM

1984

Wisard

Similar to Ntuple, but with multiple classes
One of the first commercial real-time image recognition systems

2022

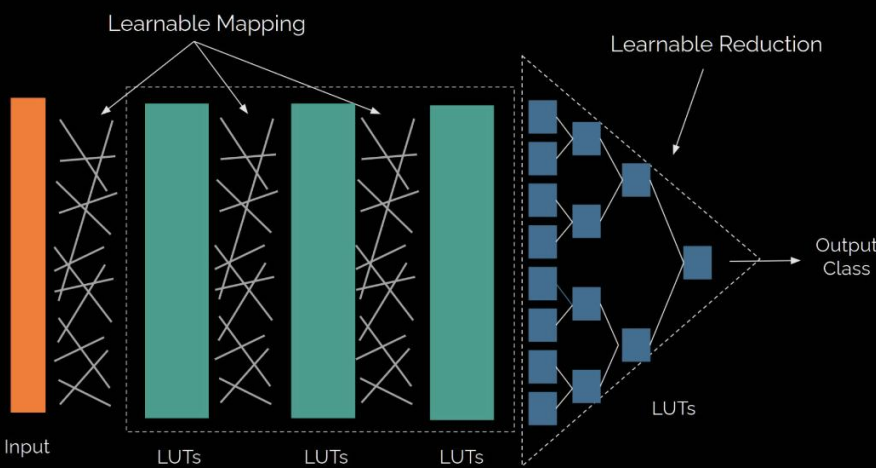

Weightless NN

Same as Wisard, but with several clever tricks

2024

Differentiable weightless NN

EFD to estimate *gradients* of LUT mapping

2016

Binary neural net

Weights are 0 or 1 (i.e. XNOR)
Accumulate result with pop count

2019

LUTNet
NullaNet

Compile a BNN efficiently in LUTs

2020

Logic net

Design for LUTs from the start

2022

Differentiable logic gate NN

No weights at all, just learn which logic gates to use

Newer developments

PolyLUT

Tree LUT

AmigoLUT

NeuraLUT

More details on different methods

| Method | Year | Key Innovation | Advance | Limitation |
|-----------|------|-------------------------------|--------------------------------|-----------------------------|
| N-tuple | 1959 | LUT pattern matching | First weightless | No generalization |
| WiSARD | 1984 | Commercial RAM-NN | Hardware, multi-class | Exponential memory |
| BNNs | 2016 | ± 1 weights, XNOR | Trainable with backprop | Still arithmetic (popcount) |
| FINN | 2017 | FPGA dataflow | Practical deployment | Arithmetic-based |
| LUTNet | 2019 | Arbitrary Boolean ops | 2 \times area efficiency | Exponential params with K |
| LogicNets | 2020 | Neurons = truth tables | Direct LUT mapping | Needs high sparsity |
| DLGNs | 2022 | Learn gate type (not weights) | Zero arithmetic | Training difficulty |
| PolyLUT | 2023 | Polynomial neurons | Fewer layers | Diminishing returns D>2 |
| DWN | 2024 | Differentiable WNNs | 135 \times energy efficiency | Tabular focus |
| NeuraLUT | 2024 | MLPs inside LUTs | Better accuracy | Complex training |

Logic gate neural networks

Construct neural network from logic gates
instead of nodes, we have logic gates

Convert the input to a binary representation
different representations can produce different results

Each node receives two inputs
The connections are randomly initialised

Outputs are summed so we can classify or
regress

$$\hat{y}_i = \sum_{j=i \cdot n/k + 1}^{(i+1) \cdot n/k} a_j / \tau + \beta$$

Labels for the equation:

- \hat{y}_i : Final output
- i : Output dimension
- n : Number of output neurons
- k : Neuron output
- τ : Normalisation temperature
- β : Optional offset

Video adapted
from [\[4\]](#), made by Felix
Petersen et al.

Why it is fast

At inference each 16 gate block is replaced by most
probable gate

Binary computations are fast

Compiler can optimise the binary logic

No matrix multiplications!

Problem: logic gates aren't differentiable

Most ML is done with gradient descent

Gradient descent needs differentiable variables

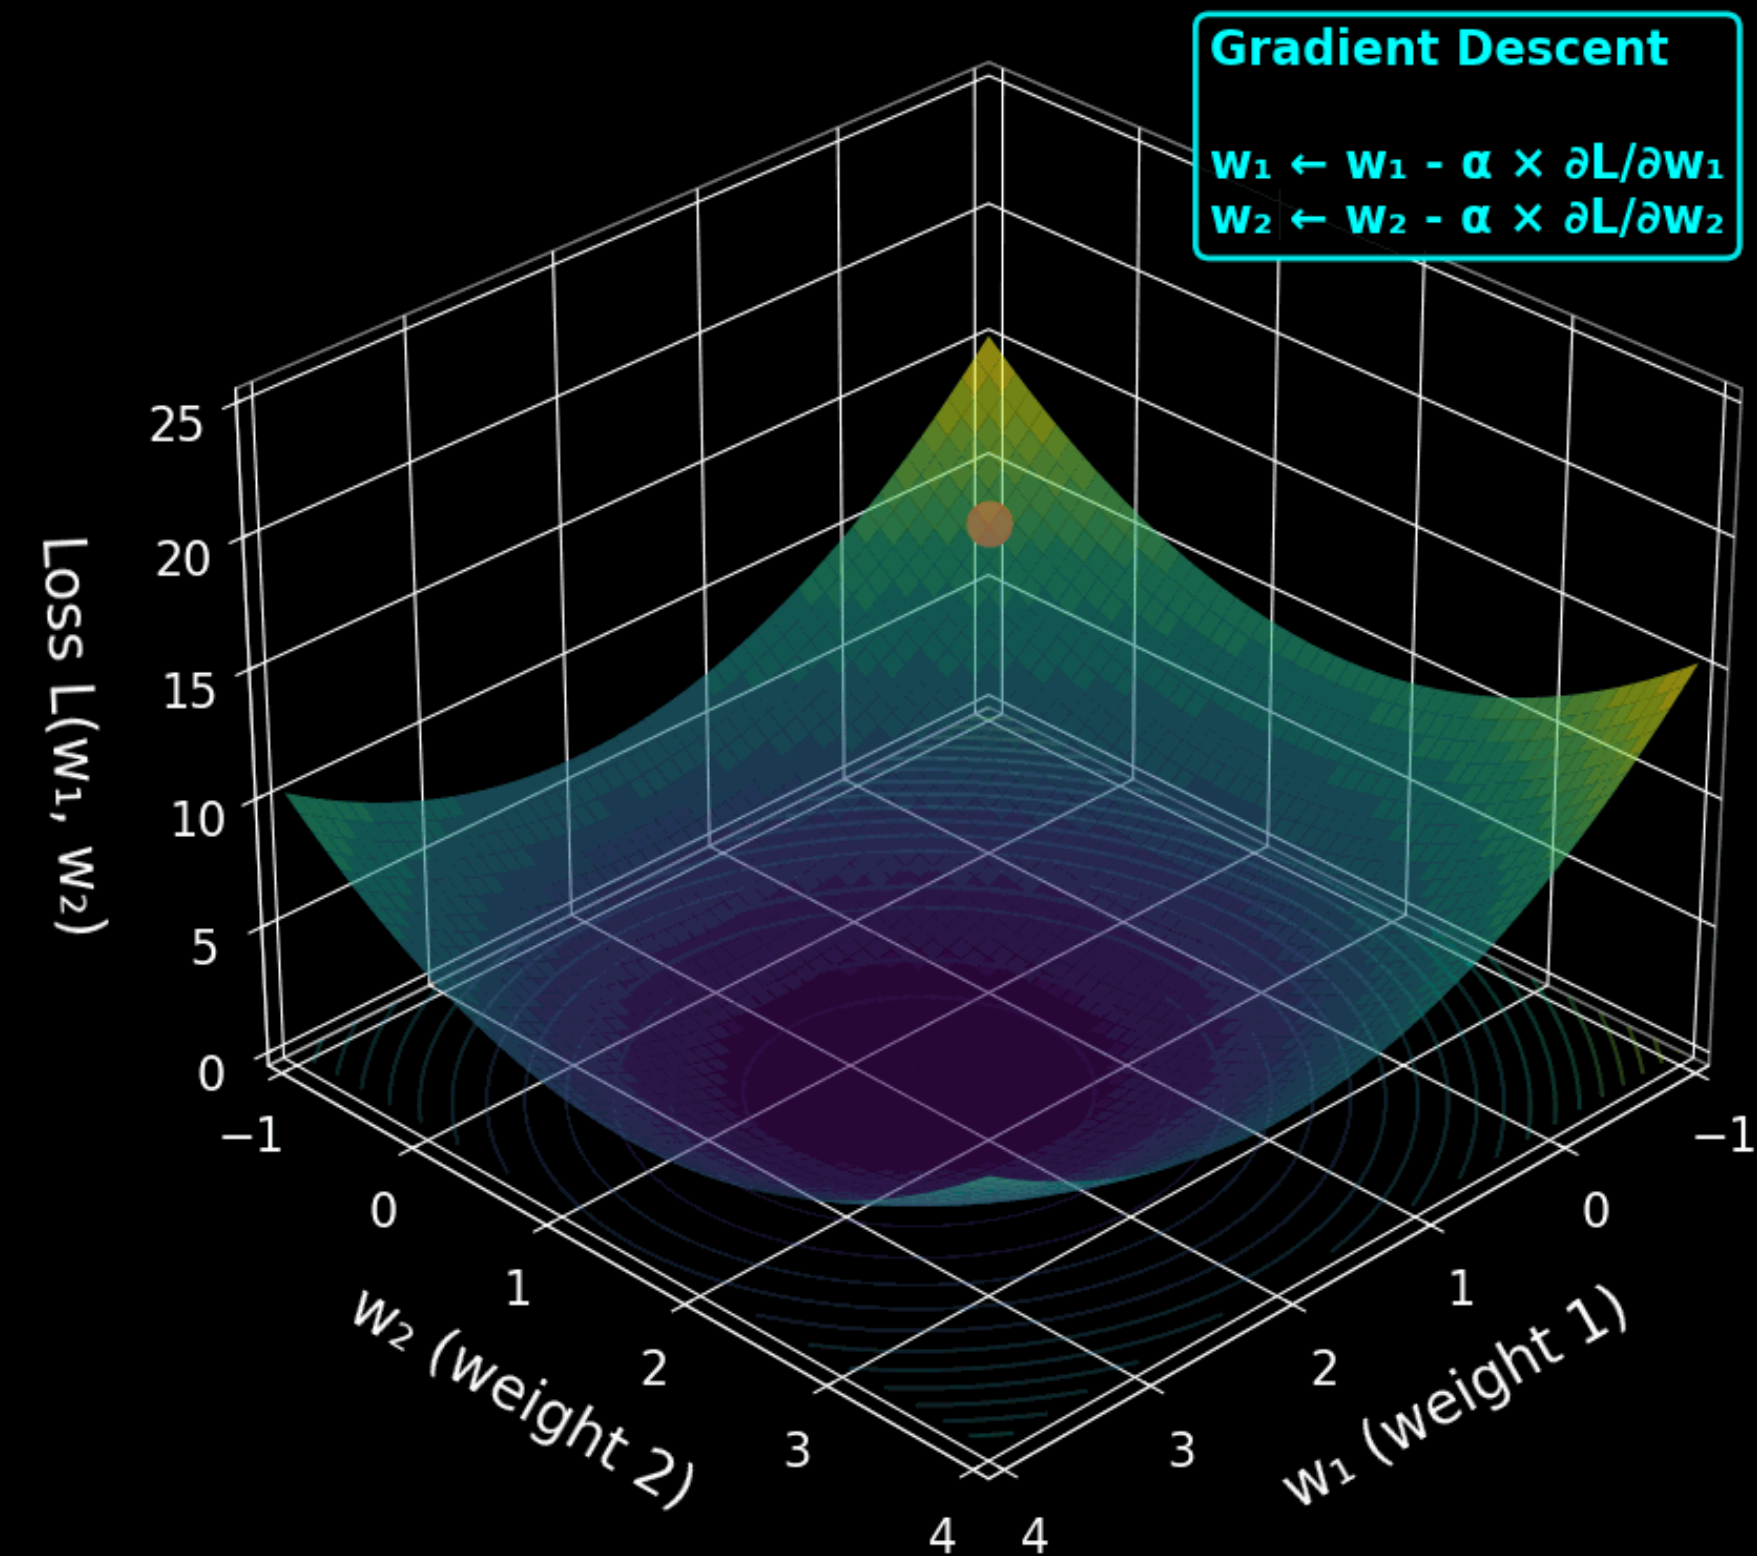

Logic gates aren't differentiable

AND gate

$$f(A, B) = \begin{cases} 1, & A = 1 \text{ and } B = 1 \\ 0, & \text{otherwise} \end{cases}$$

$\Rightarrow \frac{\partial f}{\partial A}$ and $\frac{\partial f}{\partial B}$ are not defined

Making it differentiable

Gate operations are continuous approximations
This is how we make it differentiable

Softmax of the 16 gate blocks
This is how we learn which gate is best for inference

During training evaluate 16 gates for each “neuron”
slow training, but quick inference when we replace each block of 16 with the most probable gate

Learnable weights

Neuron output

$$a' = \sum_{i=0}^{15} \frac{e^{w_i}}{\sum_j e^{w_j}} \cdot f_i(a_1, a_2)$$

Logic gate operation

| ID | Operator | real-valued | 00 | 01 | 10 | 11 |
|----|-------------------------|---------------------|----|----|----|----|
| 0 | False | 0 | 0 | 0 | 0 | 0 |
| 1 | $A \wedge B$ | $A \cdot B$ | 0 | 0 | 0 | 1 |

Linear layers is not enough for image tasks
empirically struggled to train over 6 layers

-> Replace normal CNN kernel by a binary tree
aggregates information while keeping expressivity

One channel for each input bit
We learn the significance of each bit

Create special *Or* pooling layers
fast and only need to propagate through the maximum activations

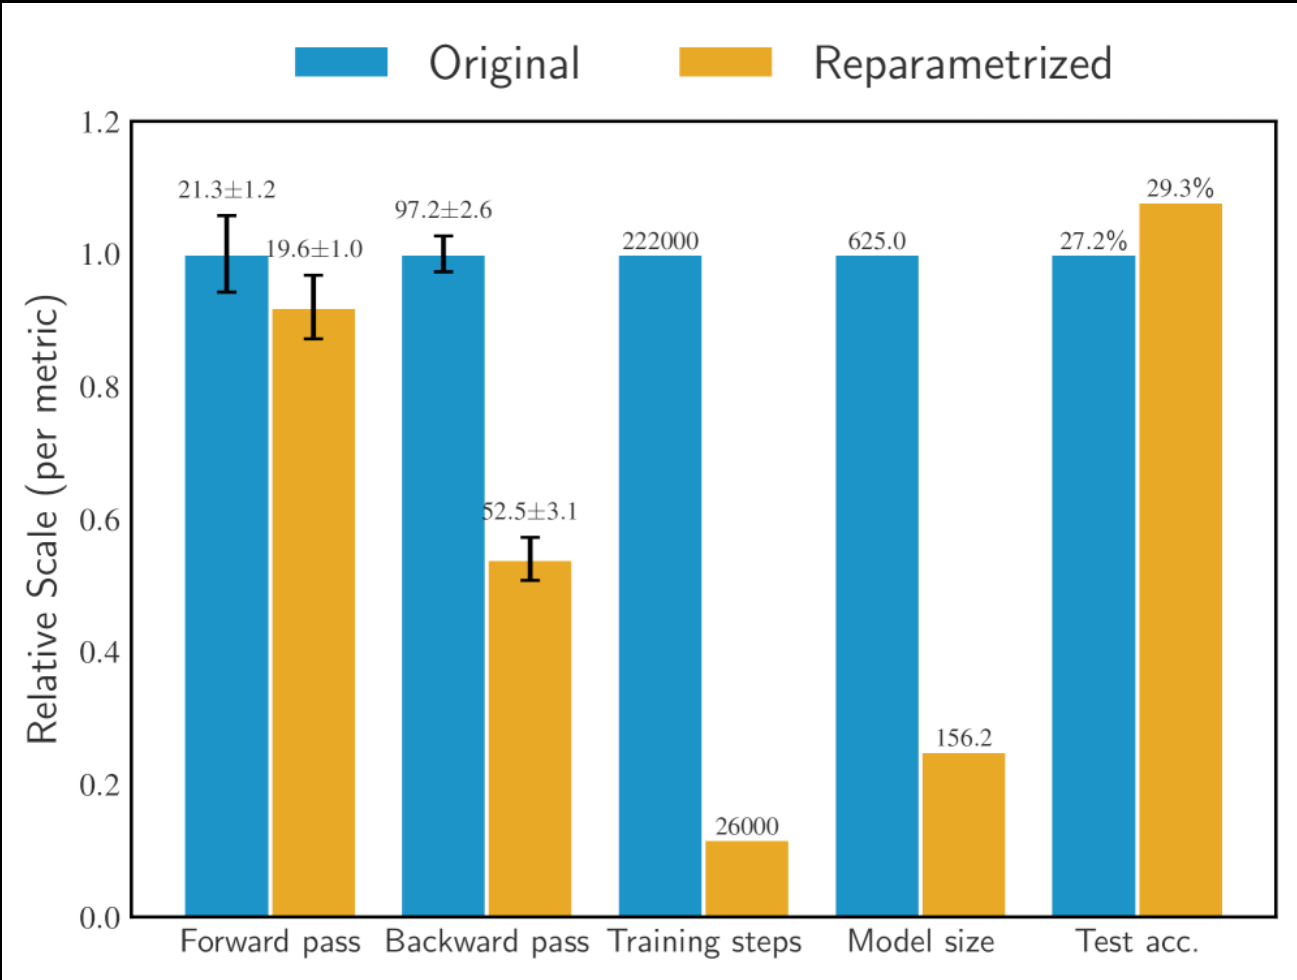

$$\perp_{max}(a, b) = \max(a, b)$$

Current state of DLGN research

New architectures: [Cellular automata](#)

[Recurrent DLGN](#)

[Reducing the number of parameters](#)

Speed records: 1 million+ MNIST inferences/second on a single CPU core

86.3% on CIFAR-10 using only 61 million logic gates

O(10-100) times smaller than state-of-the-art models at comparable accuracy

There are also several startups in this area

[NeurIPS talk](#)

Verifiability and interpretability

Normal neural networks

Interpretability and verifiability remains an open issue

Current methods often rely on approximations or is [NP hard](#)

Best tools fall short in numbers of parameters they can handle with orders of magnitude

Lots of work goes into testing LLM behaviour [[Anthropic](#), [ChatGPT](#)]

Continuous, infinite state space

LNNs

Because the states are limited, you can perform mathematical proofs ([Kresse et al](#))

You don't need to enumerate all possibilities, SAT solvers can help

Discrete, finite state space

When does ChatGPT give shorter responses?

Monday mornings

When you're rude to it

In December as compared to spring

After midnight

Which of these prompting tricks actually improves LLM performance?

Take a deep breath and think step by step

I have no fingers, please write the full code

I'll tip you \$200 for a better answer

All of the above

The model IS a Boolean circuit. Training learns the circuit structure/contents

DLGNs are very fast and show good accuracies

It has the potential to be verifiable and explainable

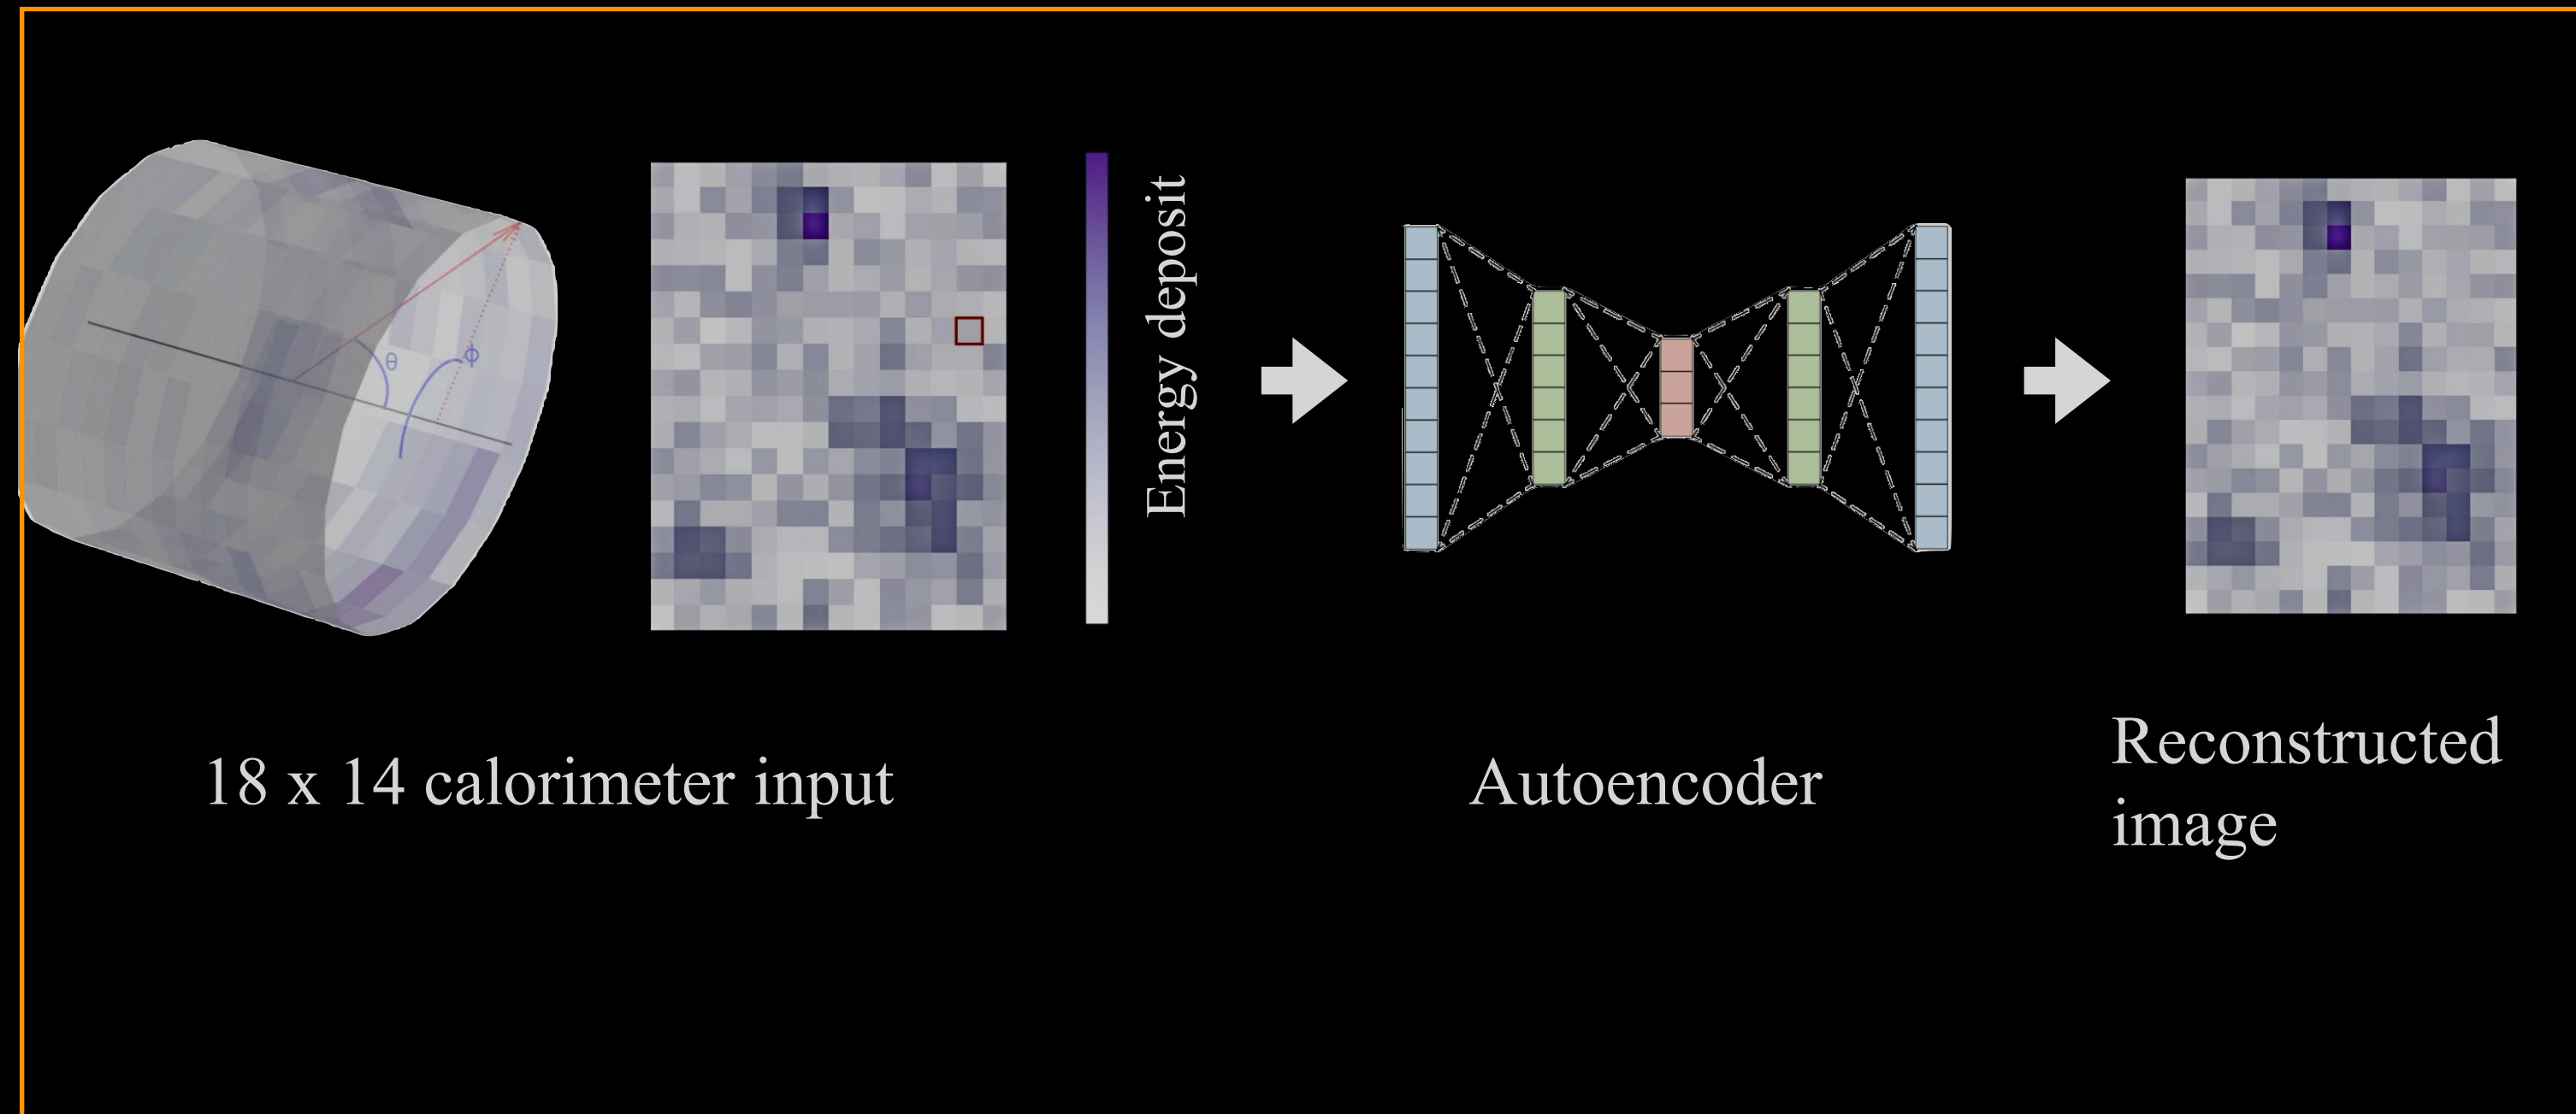

HEP applications

CICADA anomaly detection at the CMS Level-1 Trigger

Teacher

Student

Student is implemented on FPGA in the L1T which has output rate of 100 kHz

Can we achieve better physics performance or latency?

Results

Convolutional logic gate neural net outperforms baseline implementation (QKeras)

Background is Zero Bias, $t\bar{t}$ is outlier

There are three possible outlier final states, two are reserved for validation and testing

Very high anomaly scores lower since binarised inputs

This is okay, we can set the trigger threshold

A low gap between training and validation in bit mode is a sign of a good model

Results using Using 2017 CMS Open data - will be openly available very soon

Uses thermometer encodings to convert inputs to binary, described further in [\[6\]](#)

FPGA synthesis

Synthesised a logic gate deep neural net (*not convolutional*) for FPGA

Latency outperforms QKeras and HGQ* implementations

details of those can be found in [5]

We have no DSP usage since we don't have matrix multiplications

* QKeras is a quantisation package where you change precision of the weights as you are training,
High Granularity Quantisation (HGQ) lets you have different precision in each layer

EMD: [earth's mover distance](#)

This model has half the trainable parameters as the previous slide, so the physics performance suffers a bit - working on a CNN FPGA implementation underway

Vitis HLS re-place-and-route hardware cost comparison
Synthesised for AMD Virtex-7

| Model Label | Quantization Library | Latency (in cc) | DSPs | FFs | LUTs | HGQ EBOPs |
|-------------|----------------------|-----------------|------|-------|--------|-----------|
| QKeras | QKeras | 16 | 697 | 50368 | 159447 | - |
| HGQ-1E-5 | HGQ | 17 | 4 | 27776 | 111848 | 39170 |
| HGQ-1E-4 | HGQ | 11 | 1 | 6229 | 38111 | 7570 |

| LGN-LT2 | LGN | 3 | 0 | 856 | 19977 | - |

Vitis HLS estimates

Our work so far

We are maintaining and developing a python library called [torchlogix](#)

We have increased the scalability by changing binary gate representation, presented in [this paper](#) - which was shown at a NeurIPS workshop last year

Submitting an ICML paper on this topic

Also submitting an ICML position paper on the need to focus on inference speed

Potential applications in HEP

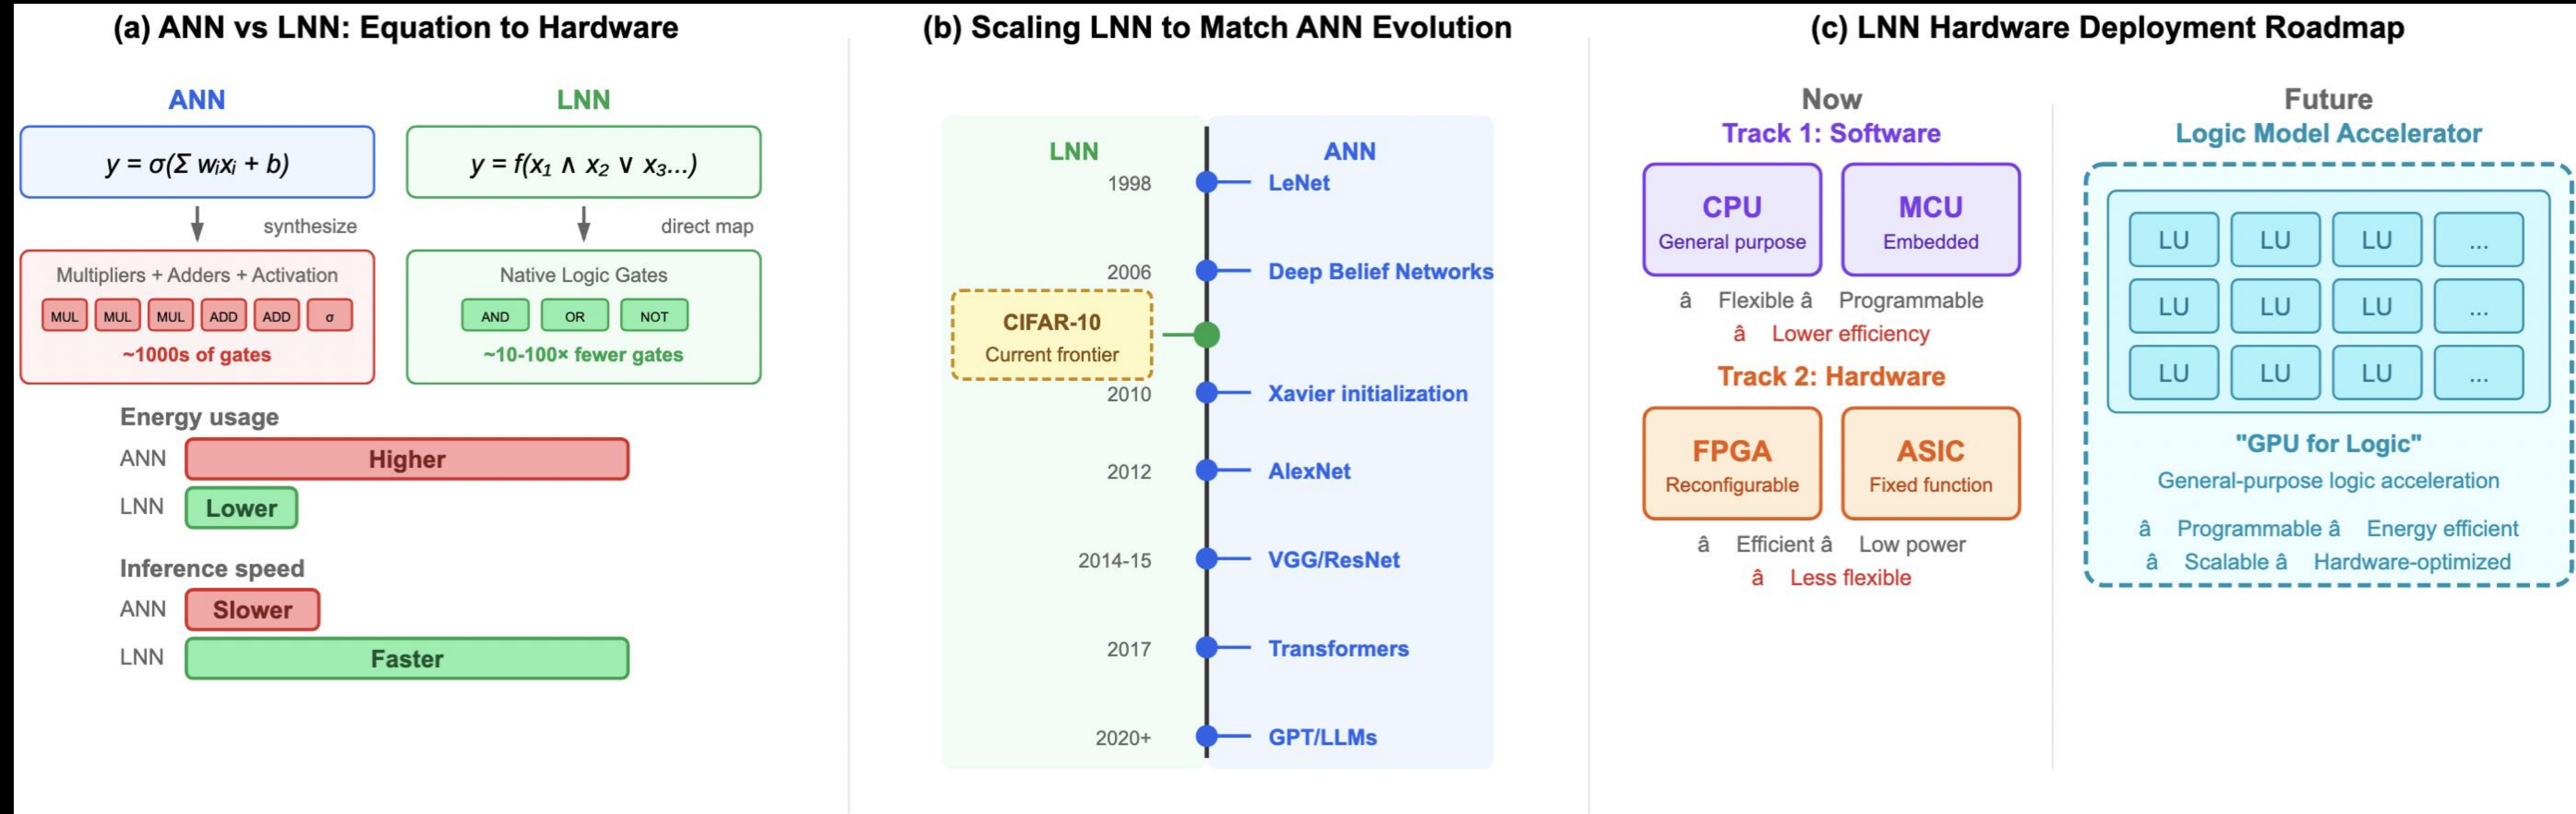

Many trigger applications - timing/accuracy tradeoff could shift

Could potentially be used directly on ASICs for FCC

Could be used for fast inference offline

Opens opportunities for physics verifiability in ML

Future of LGNs

Scaling up is the main issue:

Training can take a long time

There are gradient issues - increasing depth can harm accuracy

LNNs are fairly parameter sensitive

The FPGA tools are generally not being shared openly

Conclusion

CICADA

FPGA LATENCY

0
DSP USAGE

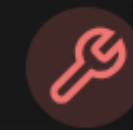

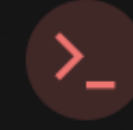

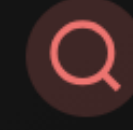

~ 0.91
AUC (CICADA)

30-60%
MODEL COMPRESSION

✓ STRENGTHS

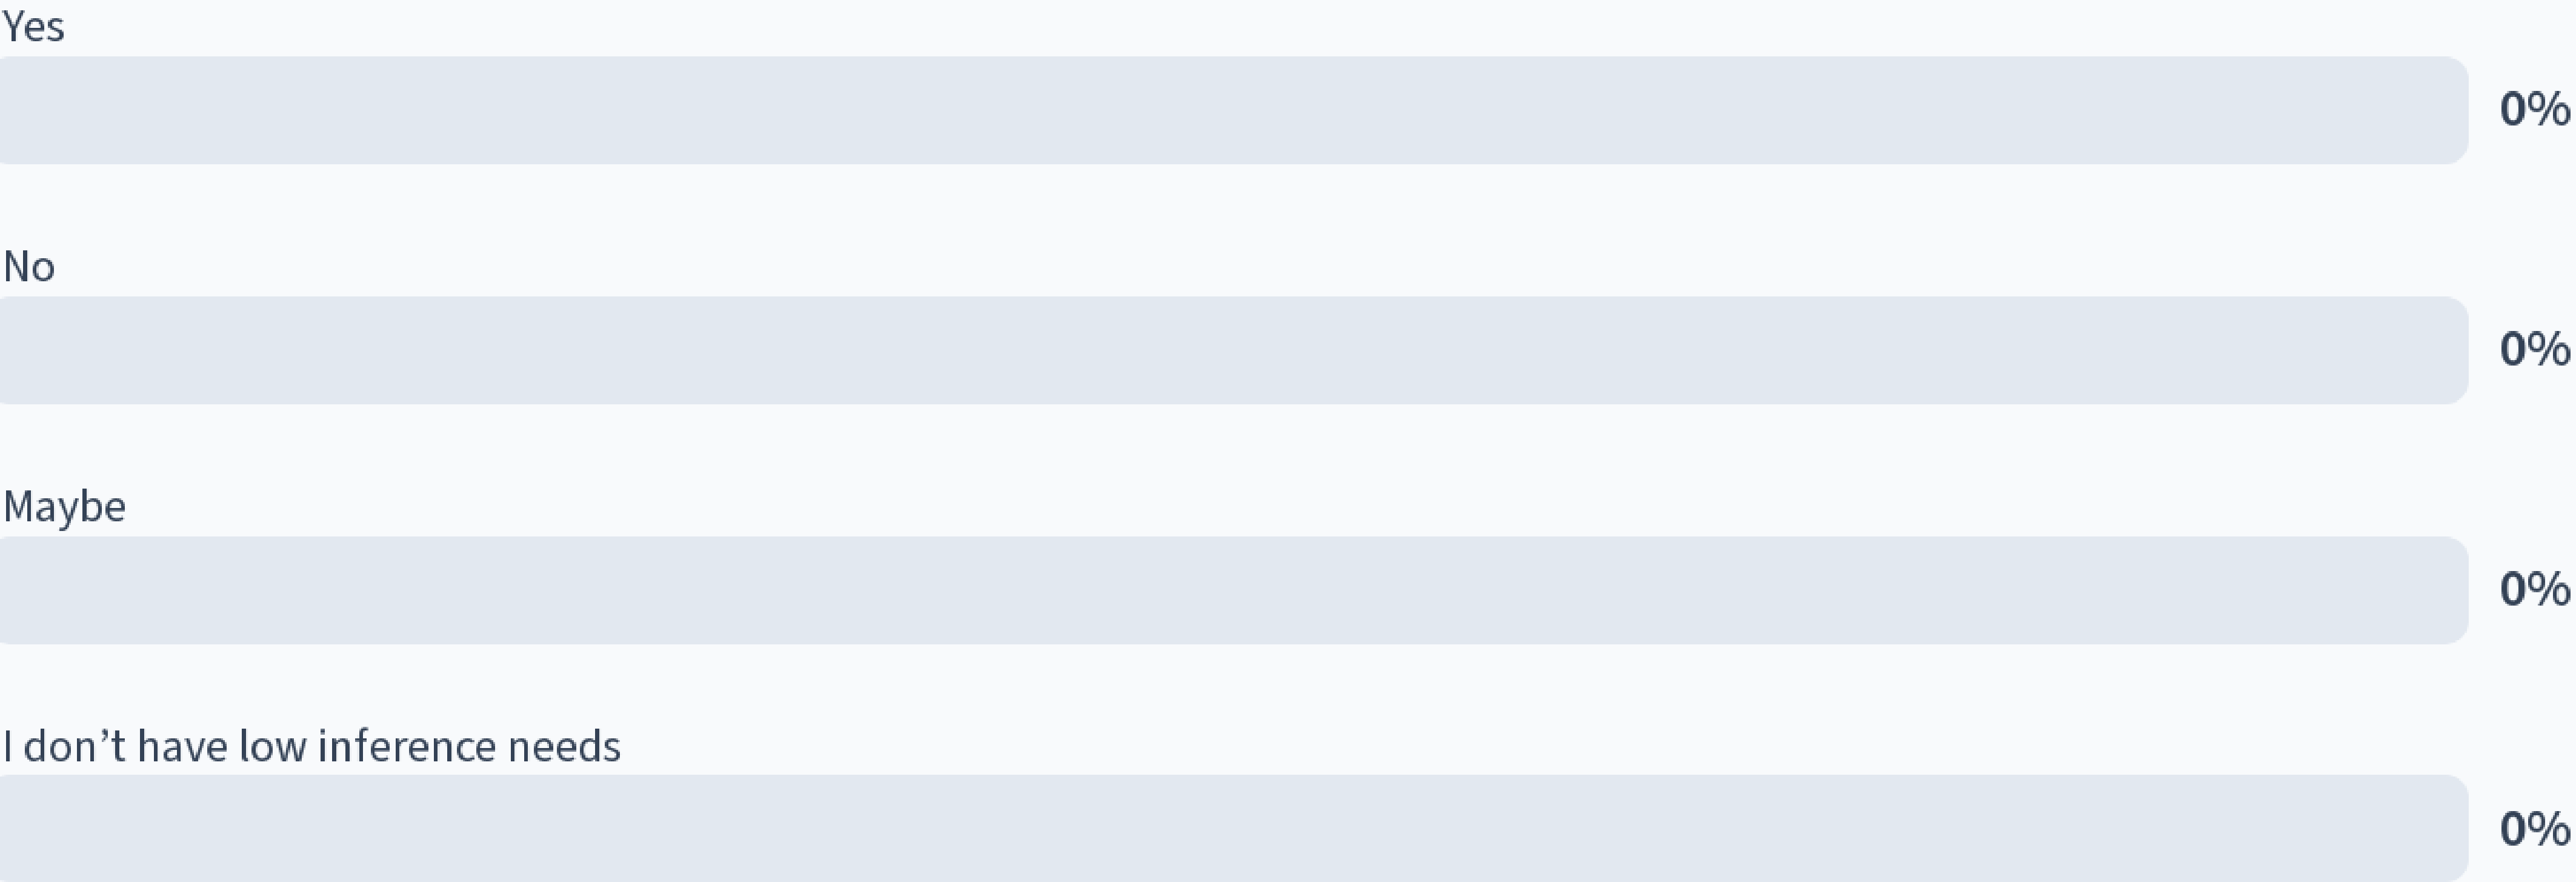

-  **No Matrix Multiply → Fast**
Binary logic operations only, no expensive floating-point arithmetic
-  **Maps Directly to FPGA LUTs**
The trained model IS a Boolean circuit — no translation needed
-  **Deterministic Latency**
Fixed timing, no cache misses, no surprises — ideal for triggers
-  **Interpretable**
You can read the logic — potential for mathematical verification

⌚ LIMITATIONS (Current)

-  **Harder to Train**
Training takes longer than standard NNs; gradient issues with depth
-  **Scaling Still in Progress**
Current frontier is CIFAR-10; larger problems need more research
-  **Input Encoding Matters**
Thermometer thresholds need tuning; representation affects results
-  **Less Explored**
Smaller research community than quantization/pruning methods

LGNs offer a **paradigm shift** for ultra-fast ML inference — trading training complexity for **massive deployment efficiency**.

Would you consider logic gate nerual nets for your low inference needs?

How to get started

| 15 | True | 1 | 1 | 1 | 1 | 1 |

Fully connected

Matrix multiplication in nodes

Same in training as inference

Randomly connected; each node has two inputs

Nodes evaluate logic gates

At inference, inputs are binary and only use most probable logic gate for each node

No matrix multiplication, binary logic can be simplified by compiler, binary computations faster

Thermometer thresholding

We need to convert continuous numbers to binary

We do this based on thresholds, as implemented in [\[4\]](#)

We learn the bin edges as we train
each bin checks whether the number \geq threshold
1 if it is, 0 otherwise

Our representation matters
the best edges will depend on the problem

In our case, we let it change, then freeze it
we use a 6 bit representation
one of the bins settles on a high threshold - likely to capture
high anomaly scores

WARP-LUTS

Example: 2-input logic gates In the special case of two inputs (a, b) , every binary logic gate admits a decomposition with only four coefficients:

$$f(a, b) = \text{sign}(c_0 + c_1 a + c_2 b + c_3(a \cdot b)),$$

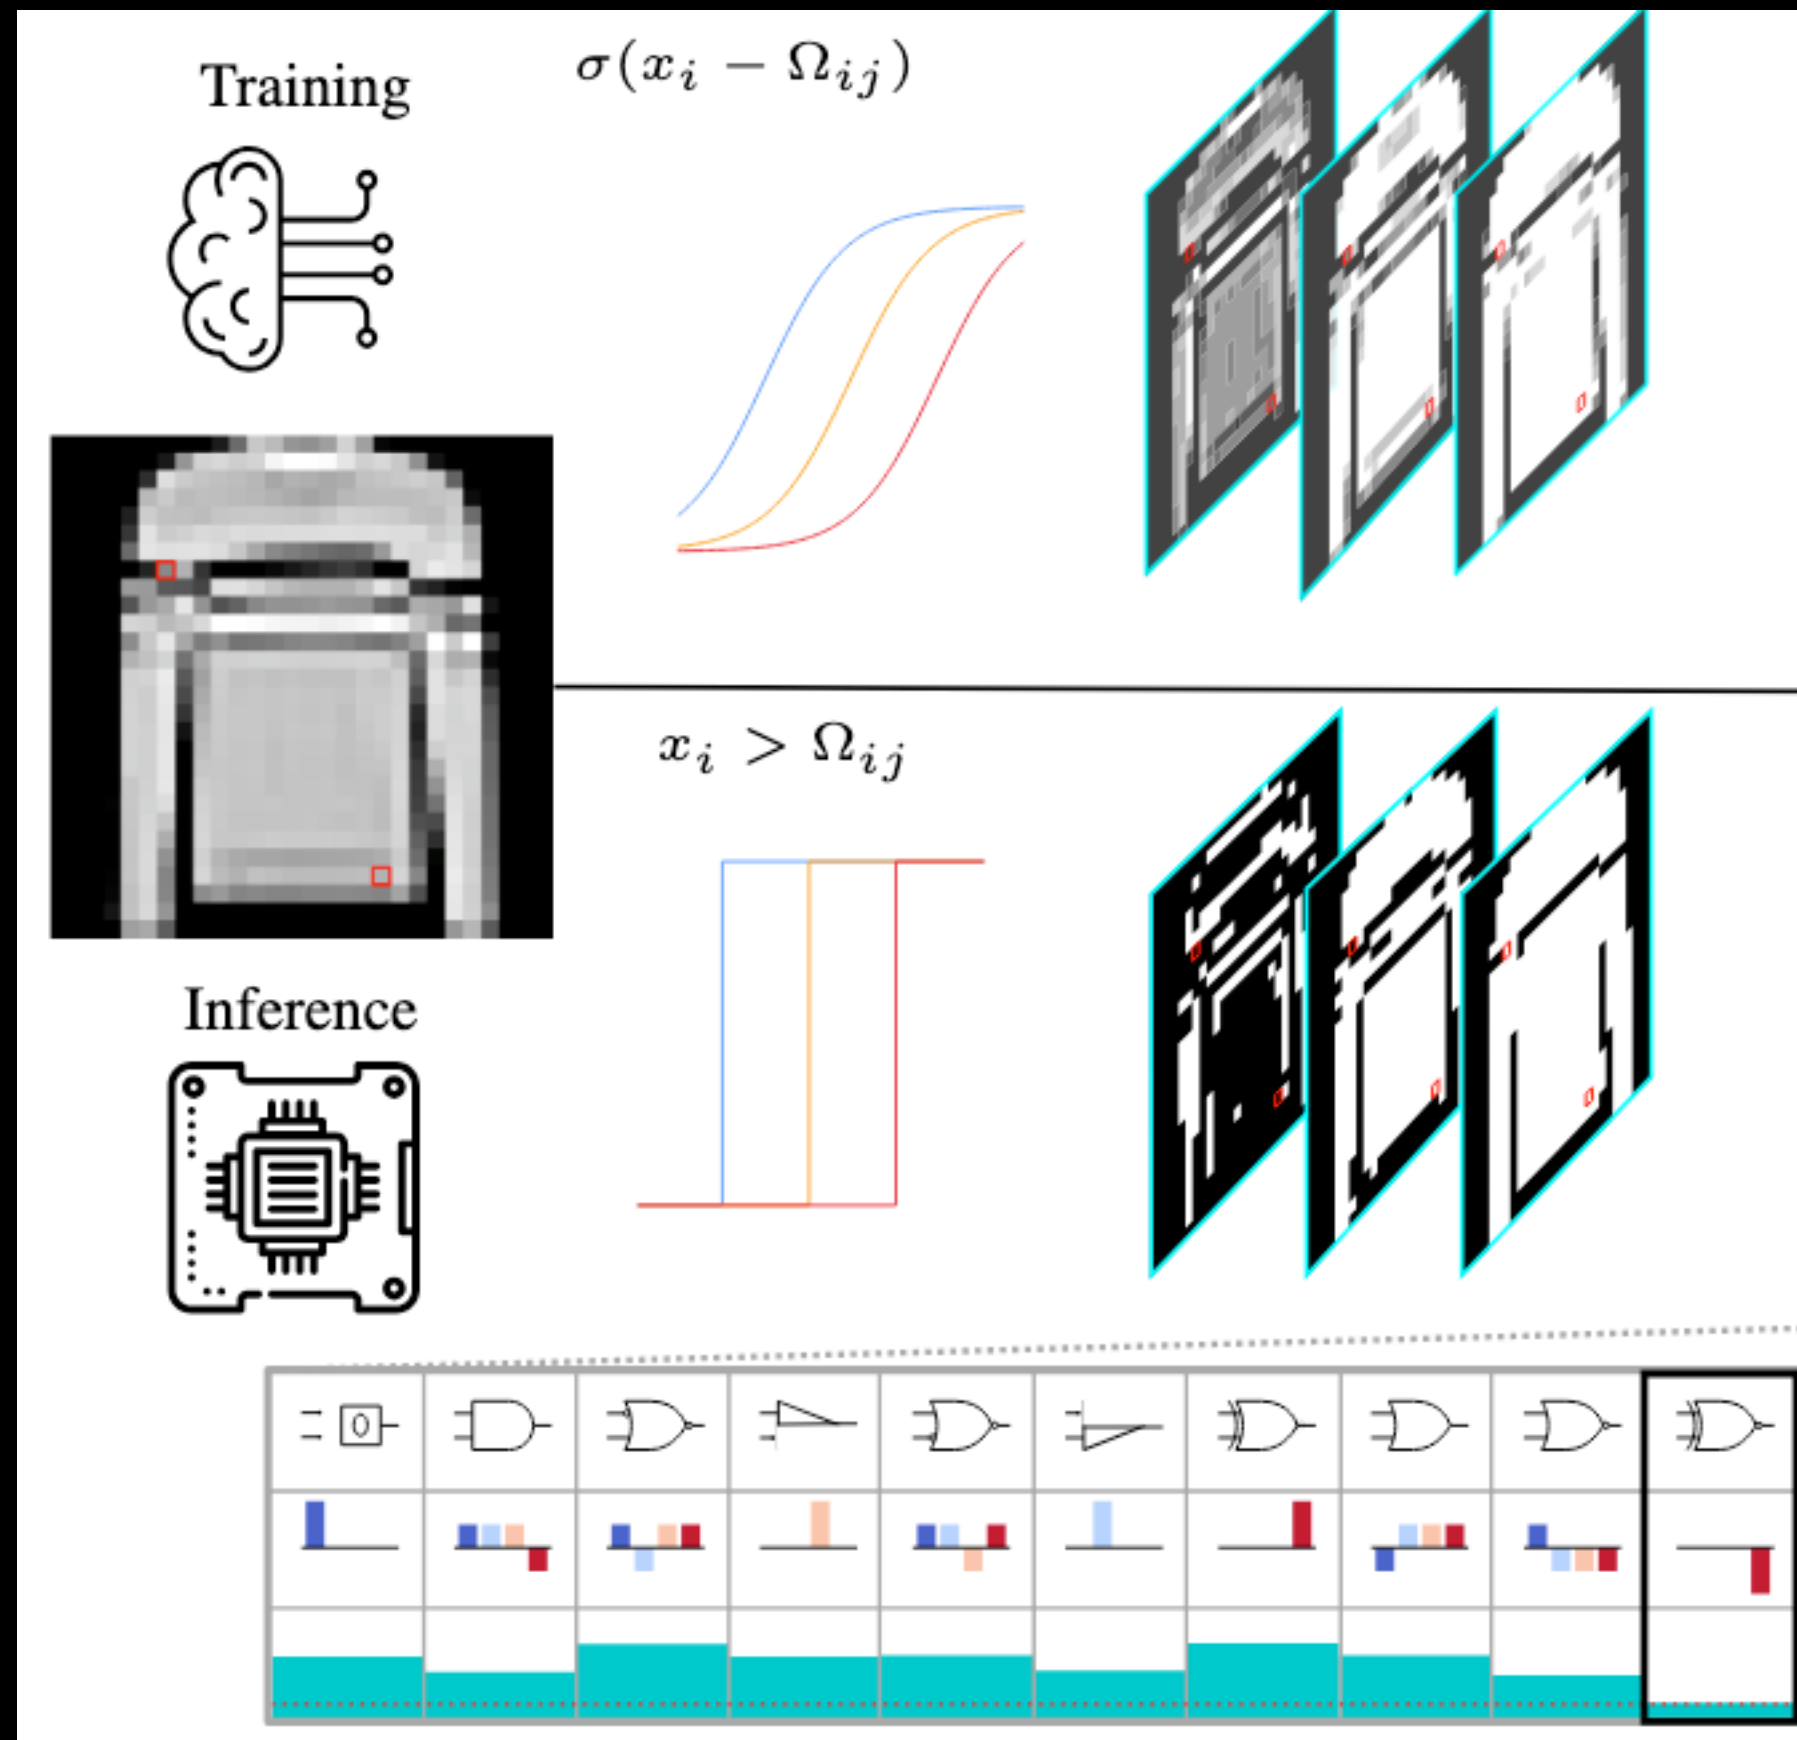

where c_0 encodes the constant bias (tendency toward 0 or 1), c_1 and c_2 encode dependence on the individual inputs, and c_3 encodes the interaction term between the inputs. For example, the coefficients $(c_0, c_1, c_2, c_3) = (0, 0, 0, -1)$ correspond to the XOR gate, while the AND gate can be expressed as $(c_0, c_1, c_2, c_3) = (-\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \frac{1}{2})$. This decomposition demonstrates that instead of enumerating all 16 binary gates explicitly, one can parameterize them compactly with just four WH coefficients (see Table [1](#) in Sec. [B](#) for the full list of gates and coefficients).

Straight through estimators

Forward: $w_{\text{binary}} = \text{sign}(w_{\text{real}})$ # discrete

Backward: $\partial L / \partial w_{\text{real}} = \partial L / \partial w_{\text{binary}}$ # pretend $\text{sign}()$ was identity

Discretisation gap

DLGN

DLGN with Gumbel noise

Reducing discretisation gap

Scaling issue with LUTs

If you have a computation like:

$$Y = A \text{ AND } B \text{ AND } C \text{ AND } D \text{ AND } E \text{ AND } F \text{ AND } G \text{ AND } H$$

Most LUTs take 4 or 6 inputs, so it can't all be contained in one LUT ->

$$(A \wedge B \wedge C \wedge D \wedge E \wedge F) \rightarrow \text{LUT1}$$

$$(G \wedge H) \rightarrow \text{LUT2}$$

$$(\text{LUT1} \wedge \text{LUT2}) \rightarrow \text{LUT3}$$

Most LUTs take 4 or 6 inputs, so it can't all be contained in one LUT -> superlunar scaling with input

Gradient issues with LNN

DLGNs are sensitive to the initialisation - part of the reason is that logic gates can symmetrically cancel out

Each logic gate reduces the gradient strength, so deep neural networks struggle

DWNs only estimate gradients - can scale badly with parameters and be slow to converge
