

# A shortcut to new physics: using the archive of LHC measurements to constrain new physics

L. Corpe (UCL) for the CONTUR team

RAL seminar, 2nd Sept 2020

- Our recent paper used CONTUR [arxiv] reinterpretation software to test a whole class of new physics models which involve "vector-like quarks" (VLQs)
- More generally, I will motivate reinterpretation, and the CONTUR method
- I'll then use the VLQ results to illustrate the power of the method and its complementarity to the LHC search programme
- I'll end with some tips for making your LHC analysis more CONTUR-friendly !

### Abstract

Quark partners with non-chiral couplings appear in several extensions of the Standard Model. They may have non-trivial generational structure to their couplings, and may be produced either in pairs via the strong and EM interactions, or singly via the new couplings of the model. Their decays often produce heavy quarks and gauge bosons, which will contribute to a variety of already-measured "Standard Model" cross-sections at the LHC. We present a study of the sensitivity of such published LHC measurements to vector-like quarks, first comparing to limits already obtained from dedicated searches, and then broadening to some so-far unstudied parameter regions.

# The LHC vs new physics A game of hide and seek

- World's largest proton collider - 27km ring
- Two multi-purpose experiments: ATLAS and CMS, built with orthogonal technologies
- Built to test SM and look for exotic particles or effects from new physics

- World's largest proton collider - 27km ring
- Two multi-purpose experiments: ATLAS and CMS, built with orthogonal technologies
- Built to test SM and look for exotic particles or effects from new physics

- Poses a conundrum for Experimentalist
- An LHC search paper typically covers 1 handful of models, takes a small team 1-2 years to analyse data and publish...
  - This is fine when we expect new particles in a particular form (from eg SUSY, obvious mass resonances, etc)...
  - ... but this has become inefficient now that the "lowhanging fruits" have been ruled out!
- Like checking each piece of hay individually before finding the needle
  - And we don't event know what the needle looks like!
- We need a change of approach

# **Re-interpretation** What is it, and why should we do it?

- For the last ~50 years, we've known what to look for at each step: Z boson, W boson, top quark, Higgs boson...
- Many expected SUSY particles to follow shortly after the Higgs, but now increasingly disfavoured...
- Today, we no longer have a single guiding theory to motivate discoveries, but we do have largest HEP dataset every collected
- Need a paradigm shift from top-down/ theory-driven approach to bottom-up/ data-driven approach

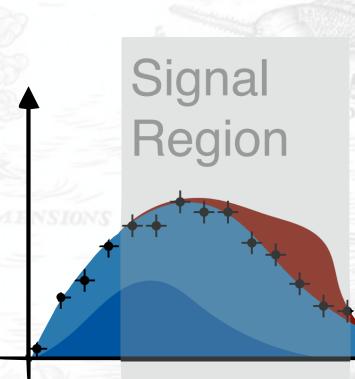

- The HEP field does not currently work efficiently in data-driven mode
- Searches take years, only to probe a handful of models...
  - ...which may already be excluded by other analyses anyway.
- This is a waste of precious person power and computing resources
- We must learn to recycle our work This is know as **re-interpretation**

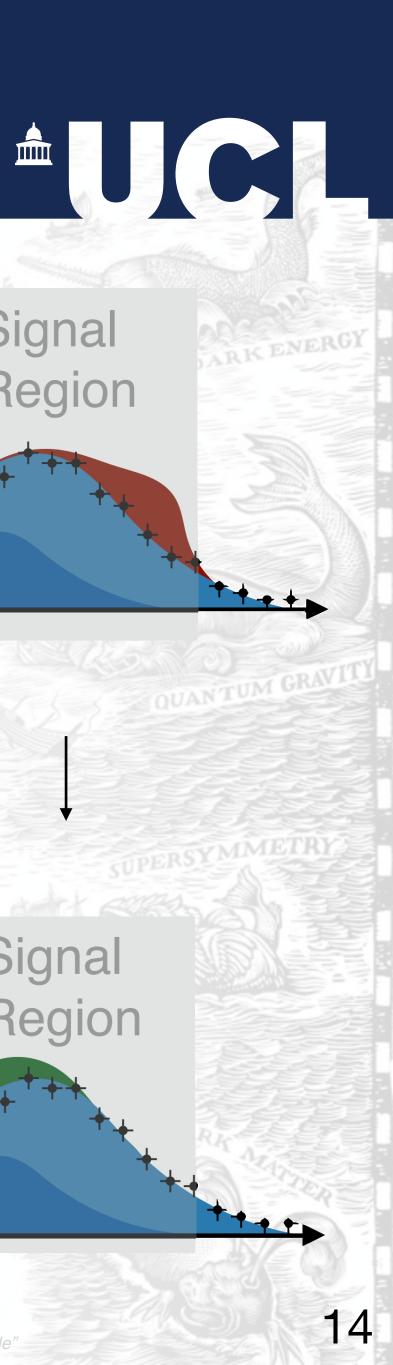

- Whether measurement or search, result of an LHC analysis is a measurement of the number of events/cross-section in a particular region of phase space.
- Compared to a background prediction from the SM. Insert prediction from a new physics model, and see if signal+SM agrees with the data. If it disagrees, signal can be excluded at some confidence level.
- Reinterpretation means preserving the analysis results such that new signals can still be tested at a later date
- This process works particularly well if the data are "unfolded" to particle-level (corrected for detector effects) so that one can easily and cheaply insert a new signal.

Signal

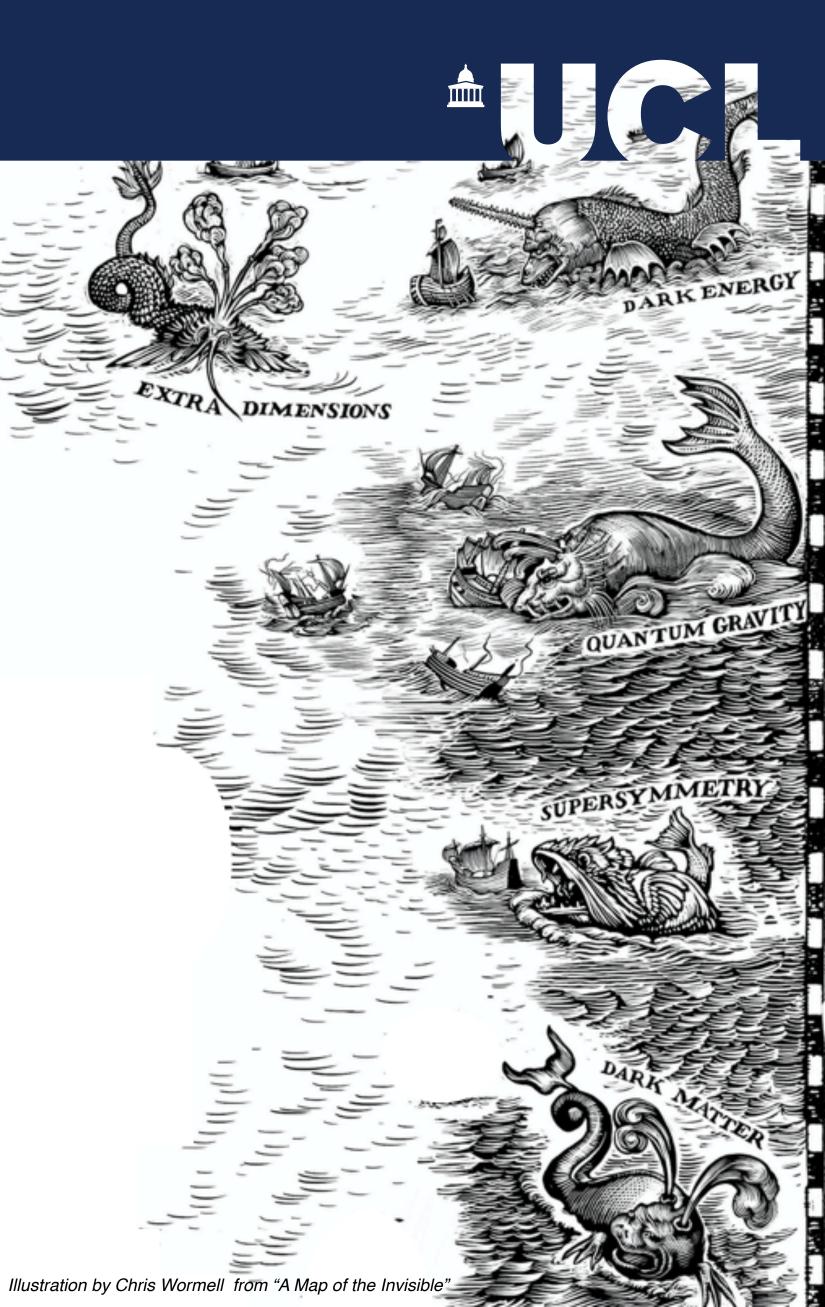

Region

# **CONTUR** (

# A tool for fast re-interpretation of LHC results

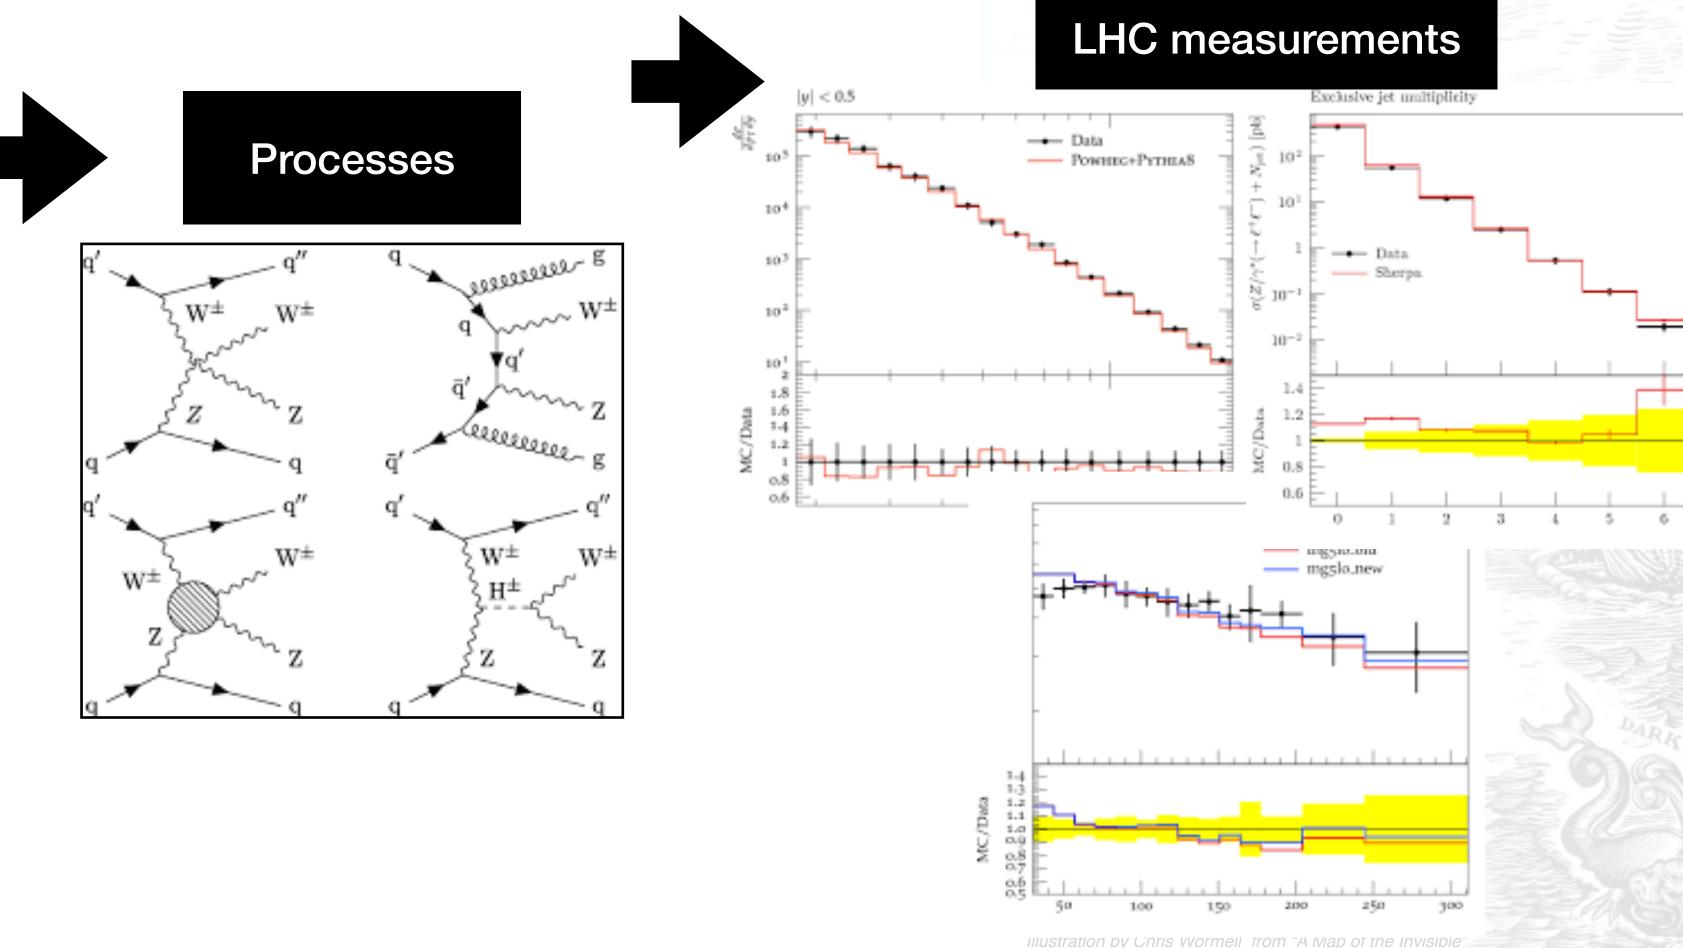

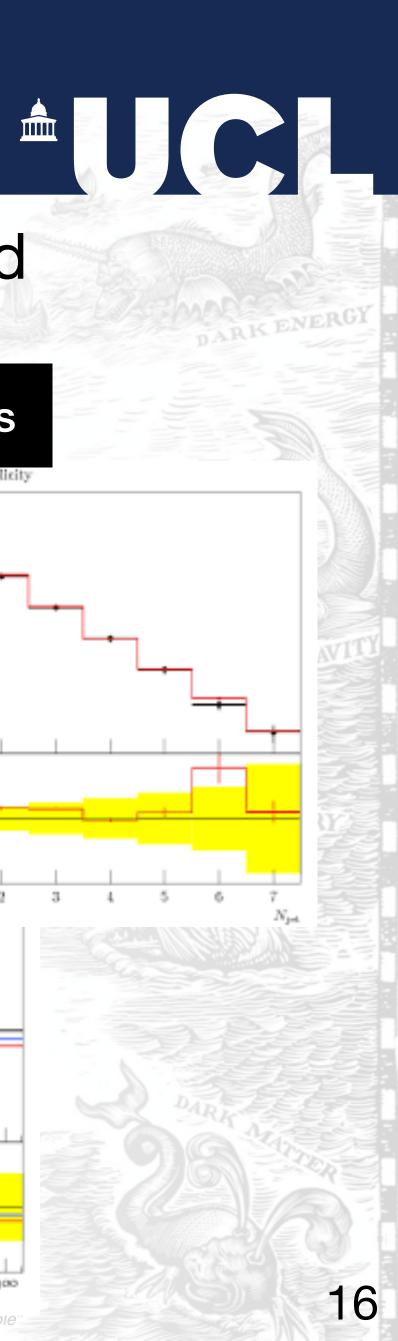

CONTUR 101

# Key idea: the SM Lagrangian is very finely balanced. You can't easily add BSM particles without the effect showing up in SM distributions

CONTUR 101

# Key idea: the SM Lagrangian is very finely balanced. You can't easily add BSM particles without the effect showing up in SM distributions

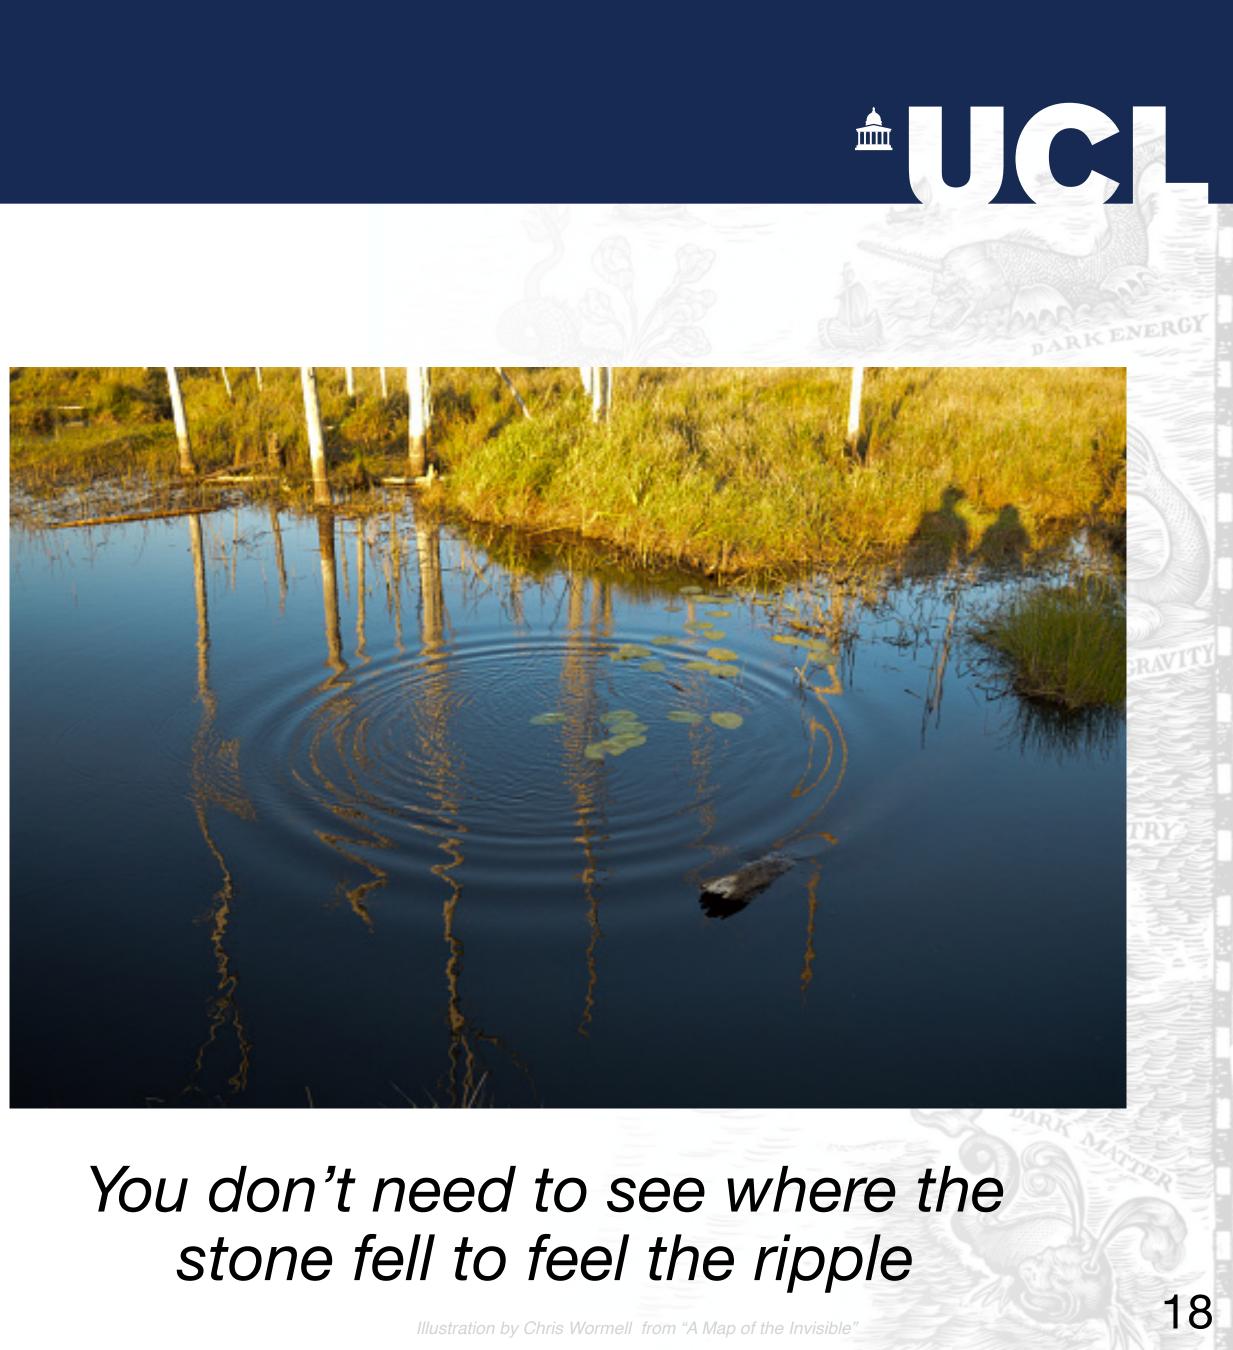

- The LHC programme often focuses on most spectacular signature of a new model...
- But many models might already be ruled out because would cause visible distortions in spectra of 'standard" processes!
  - We already have hundreds of such measurements !
- Challenge is figuring out how a model might impact hundreds of measured distributions for a given point of BSM parameter space...
- ...and understanding whether the variation is consistent with the measured data within uncertainties

- CONTUR uses bank of LHC results preserved in Rivet to rapidly check if new models are already ruled out
- Input: Universal Feynrules Object (new physics Lagrangian coded up in python by theorist)
- Herwig: generate events for all 2->2 processes involving new particles, for a given set of parameter values
- Pass through ~150 Rivet routines from particle-level LHC results
  - This is quick since everything is at particle-level!
  - Routines categorised into 'pools' grouped by  $\sqrt{s}$  and final state to ensure orthogonality
- Compare size of any deviation to reference data from HEPData (including correlations!) to check if signal would already have been seen or whether it is OK within errors -> CLs value
- CONTUR does book-keeping to repeat over arbitrary array of parameter values

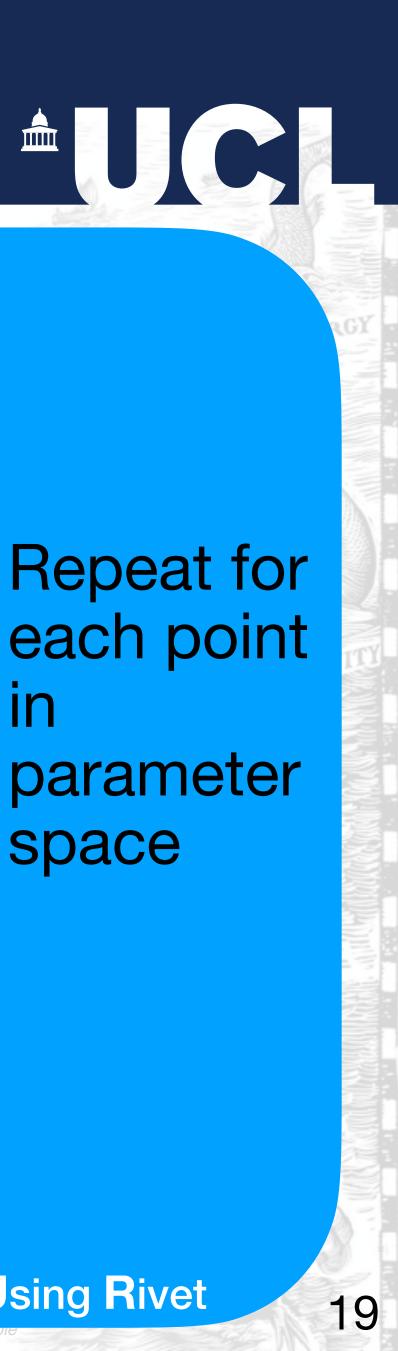

### UFO describing BSM model

Herwig: event generation for all new 2->2 processes

**Rivet+HEPdata to determine** effect of BSM on existing measurements

CLs method for exclusion

Repeat for each point In parameter space

Running 30,000 events on a grid of 200 points takes <24h on standard batch farm

A dedicated search takes 2 years, our latest paper took 3 months and probed whole range of configurations

CONTUR can address whole classes of models extremely quickly, so that ATLAS and CMS search analysts can focus on the ones which are really tricky!

# Universal FeynRules Output [2011, <u>arxiv</u>]

### Abstract

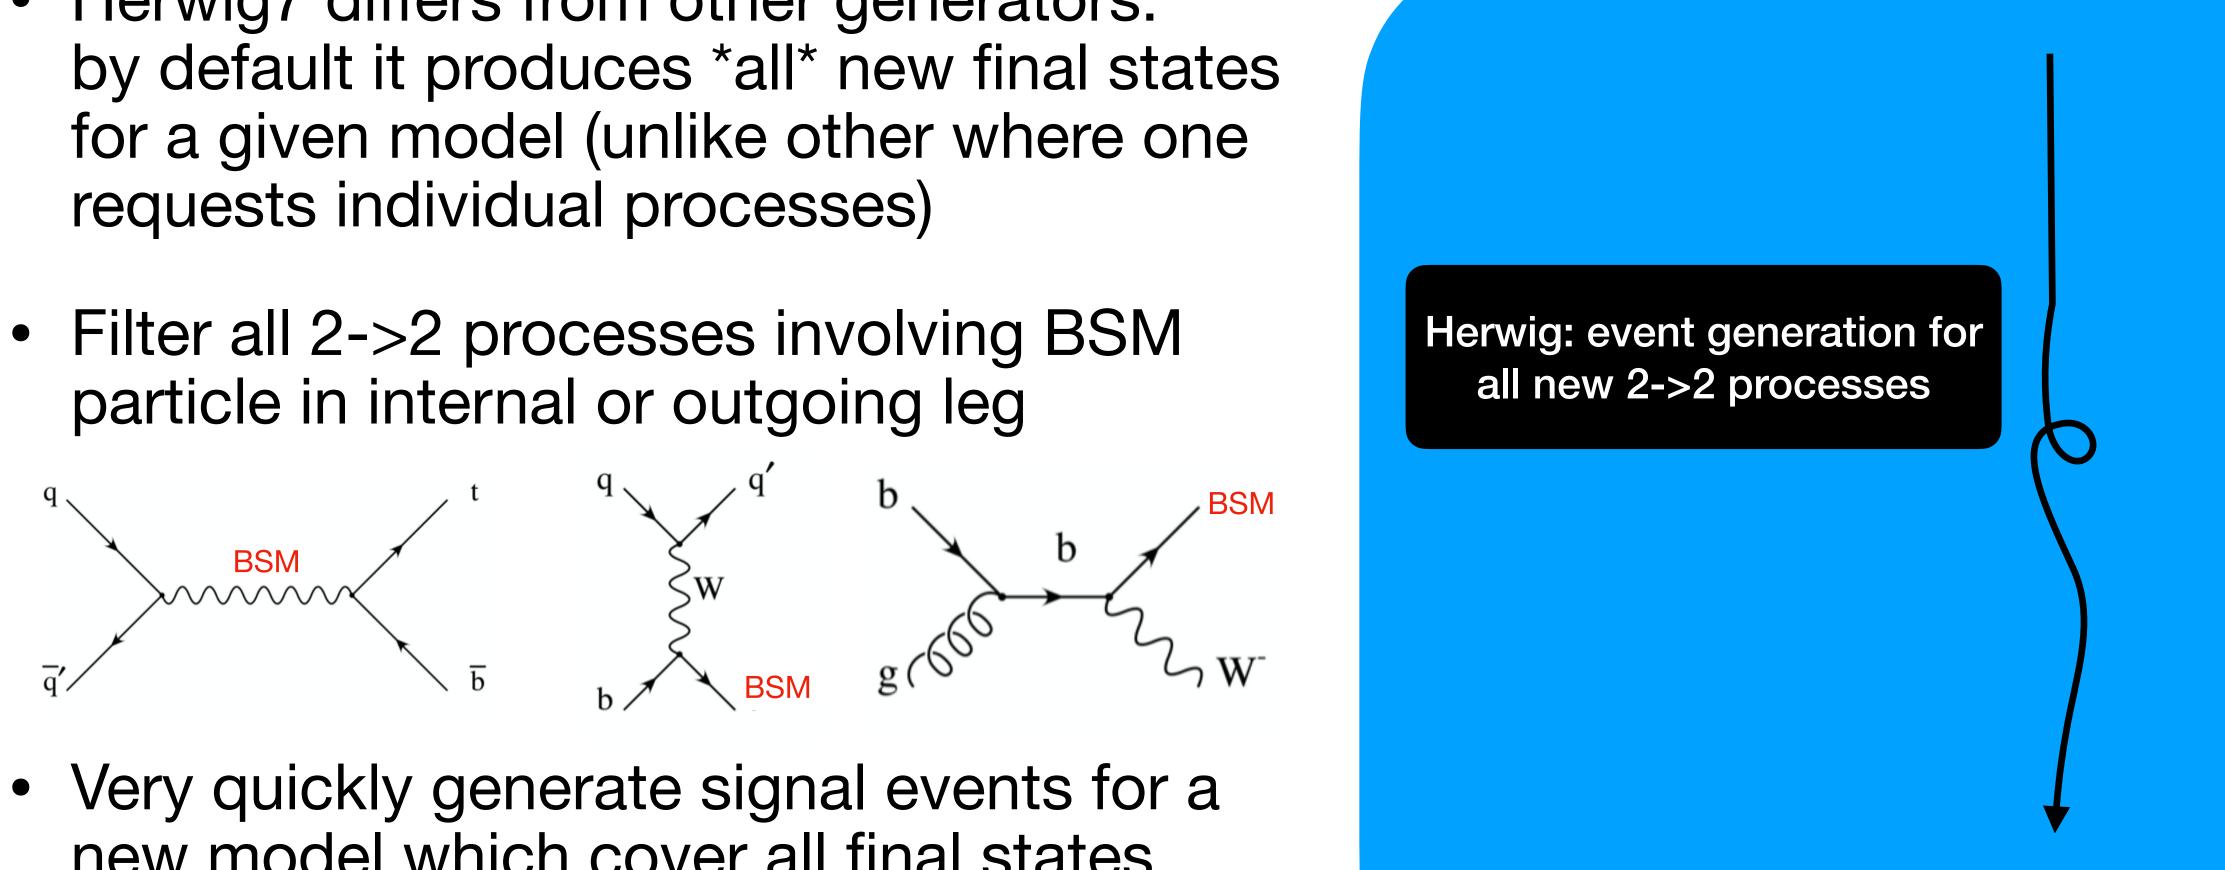

We present a new model format for automatized matrix-element generators, the socalled Universal FeynRules Output (UFO). The format is universal in the sense that it features compatibility with more than one single generator and is designed to be flexible, modular and agnostic of any assumption such as the number of particles or the color and Lorentz structures appearing in the interaction vertices. Unlike other model formats where text files need to be parsed, the information on the model is encoded into a PYTHON module that can easily be linked to other computer codes. We then describe an interface for the MATHEMATICA package FEYNRULES that allows for an automatic output of models in the UFO format.

- Database of UFOs with many new models: https://feynrules.irmp.ucl.ac.be/wiki/ModelDatabaseMainPage
- Theorists typically prepare UFOs to go with their preprints, or can do so fast. This means new models are quickly available for CONTUR study in a widely-accepted format!

- Herwig7 differs from other generators: requests individual processes)
- particle in internal or outgoing leg

new model which cover all final states, even the "boring" ones!

Louie Corpe, UCL (I.corpe@ucl.ac.uk)

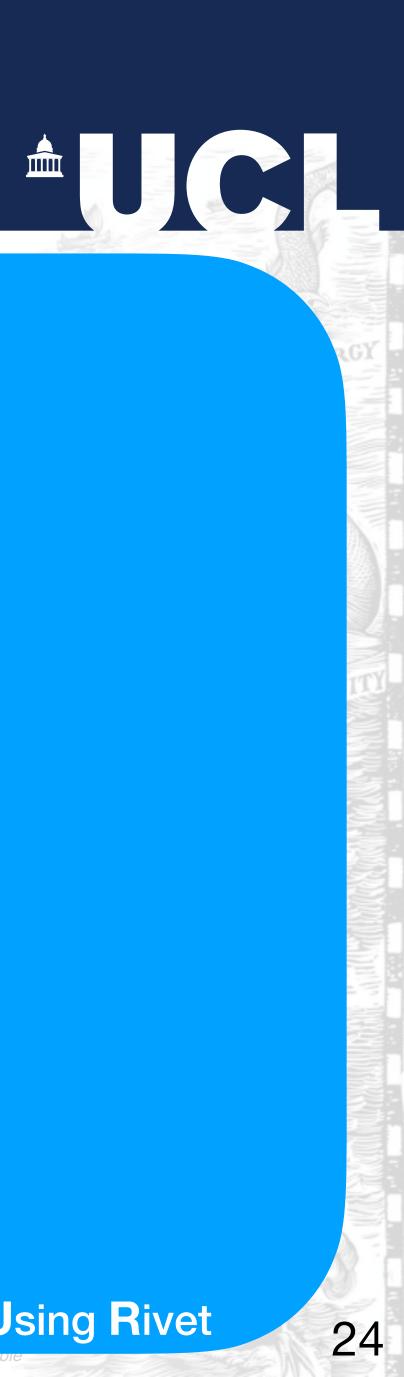

- Robust Independent Validation of Experiment and Theory (RIVET), originally for validation of event generators
- C++ code structure, allows particle-level measurements to preserve the analysis logic in a runnable plugin. Particlelevel: no detector simulation/smearing needed
- Results of measurements are already stored in HEPData in Rivet-friendly format, and synchronised with Rivet database
- It's FAST: Passing simulated events through Rivet, can run hundreds of plugins, and produce output for hundreds of distributions with negligible time cost wrt event generation
- So a generator developer can easily test new features against existing data...
- ...And we can easily test effect of new models on measured spectra from ~150 LHC analyses at 7, 8 and 13 TeV, which CONTUR places into orthogonal pools

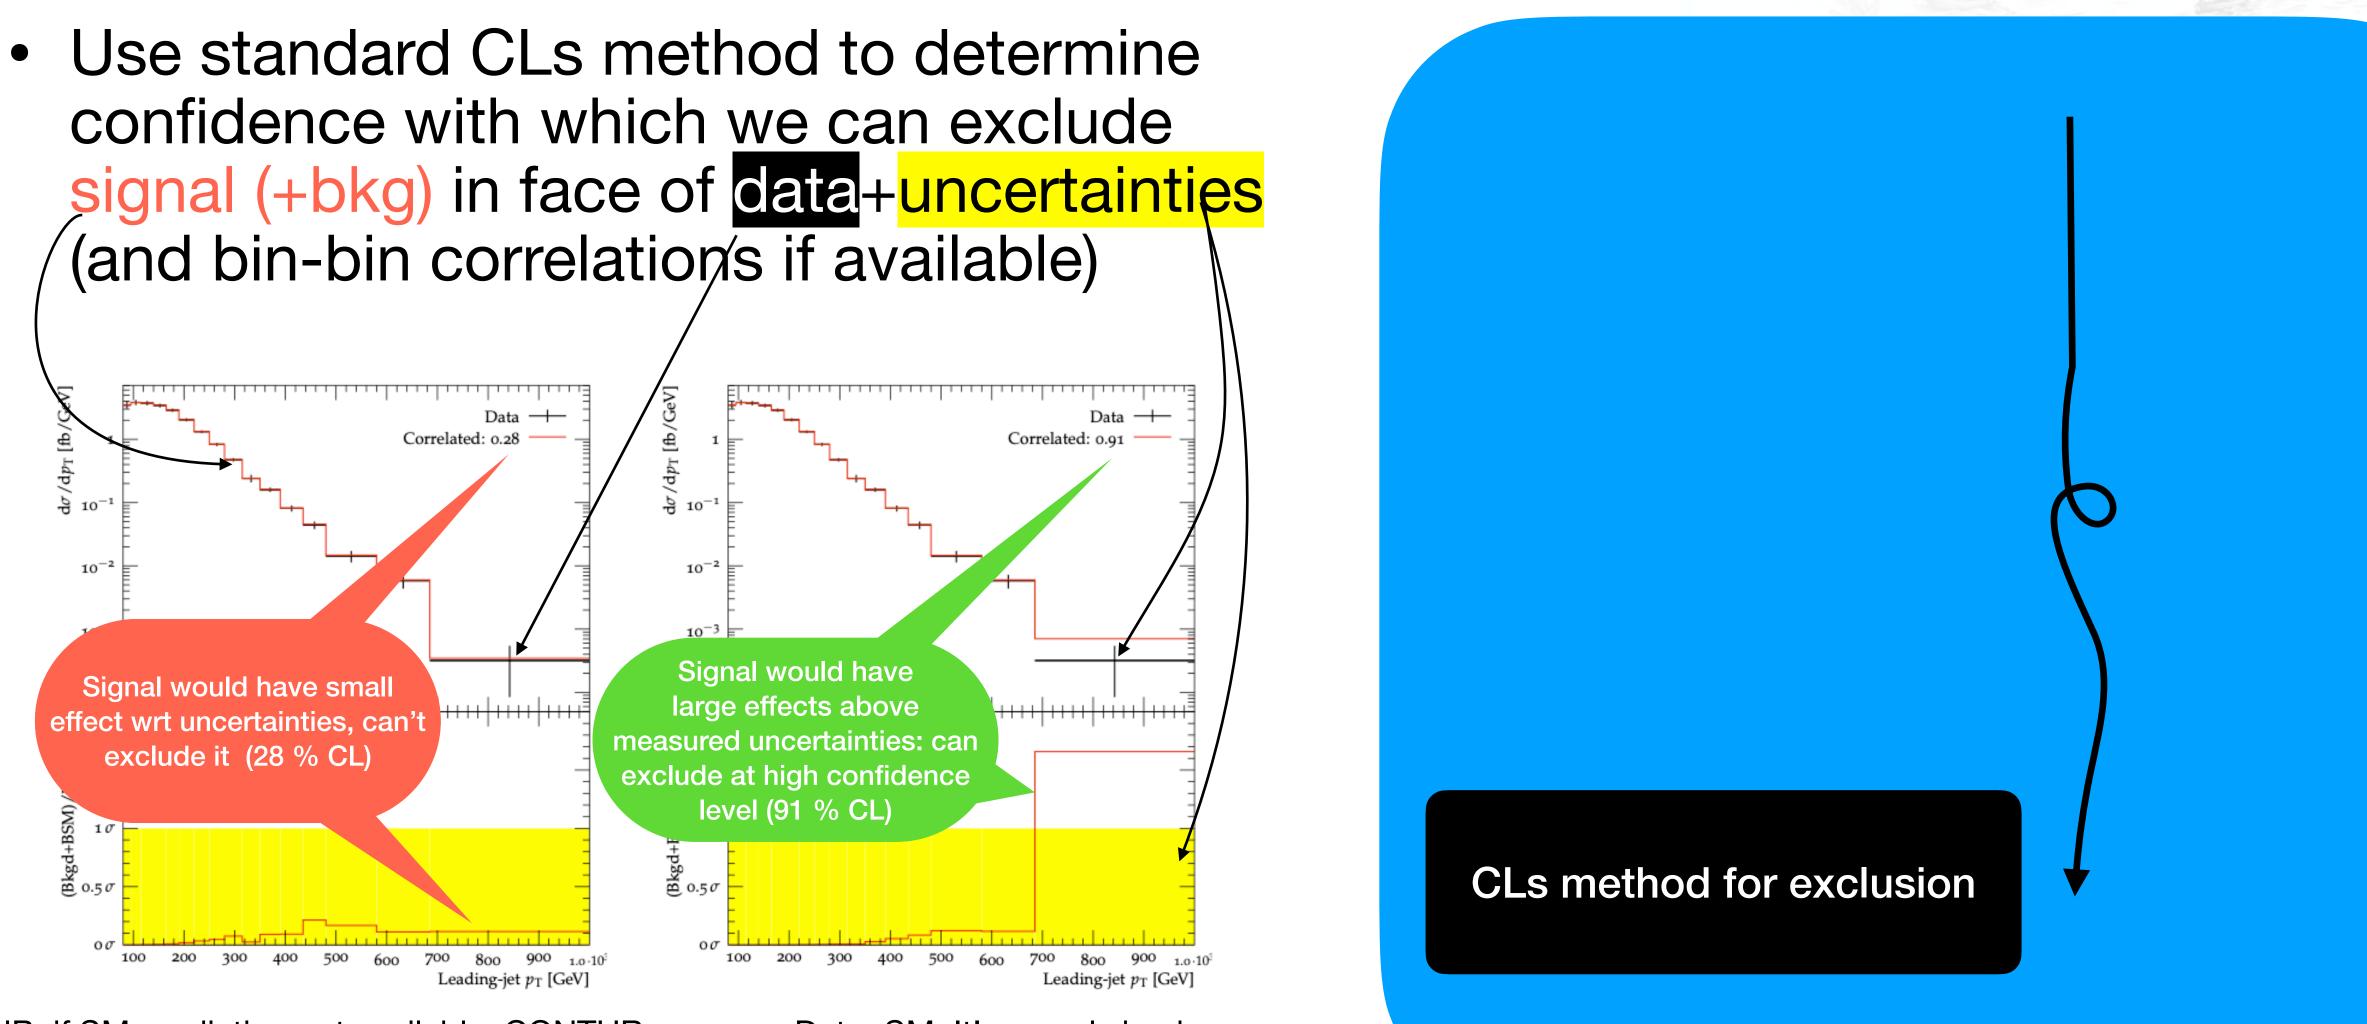

**Rivet+HEPdata to determine** effect of BSM on existing measurements

(and bin-bin correlation if available)

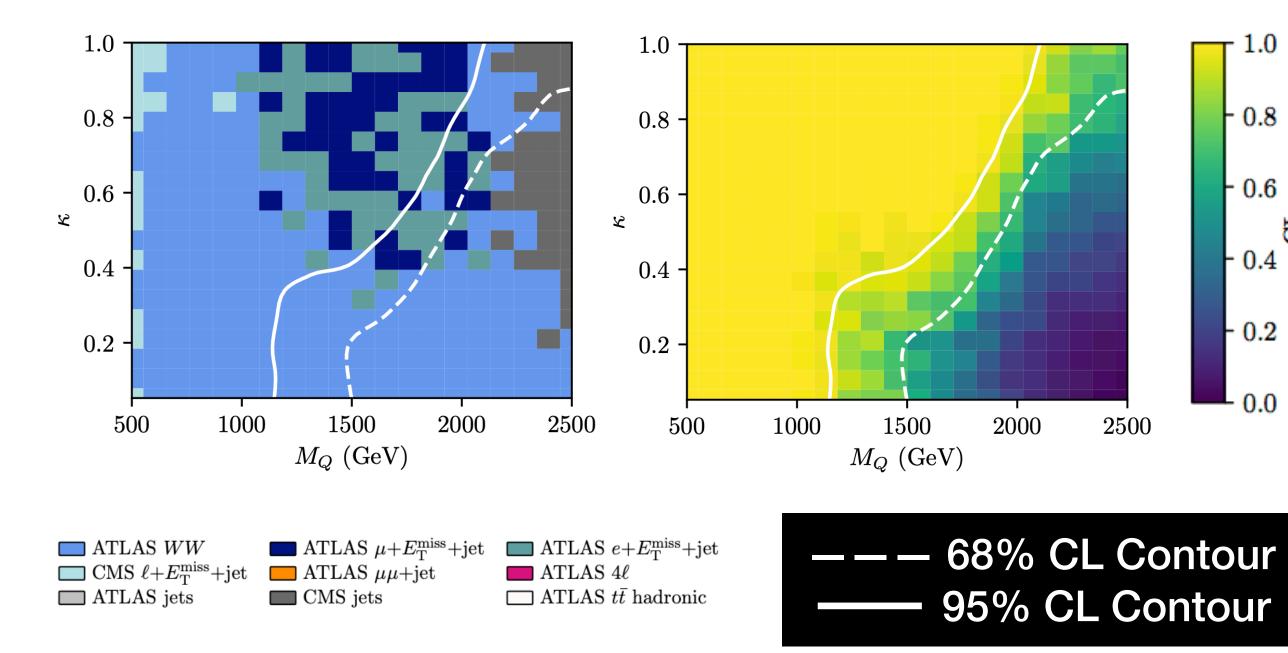

NB: if SM prediction not available, CONTUR assumes Data=SM. It's an ugly hack, but it works, since we claim no significant deviations seen at LHC so far

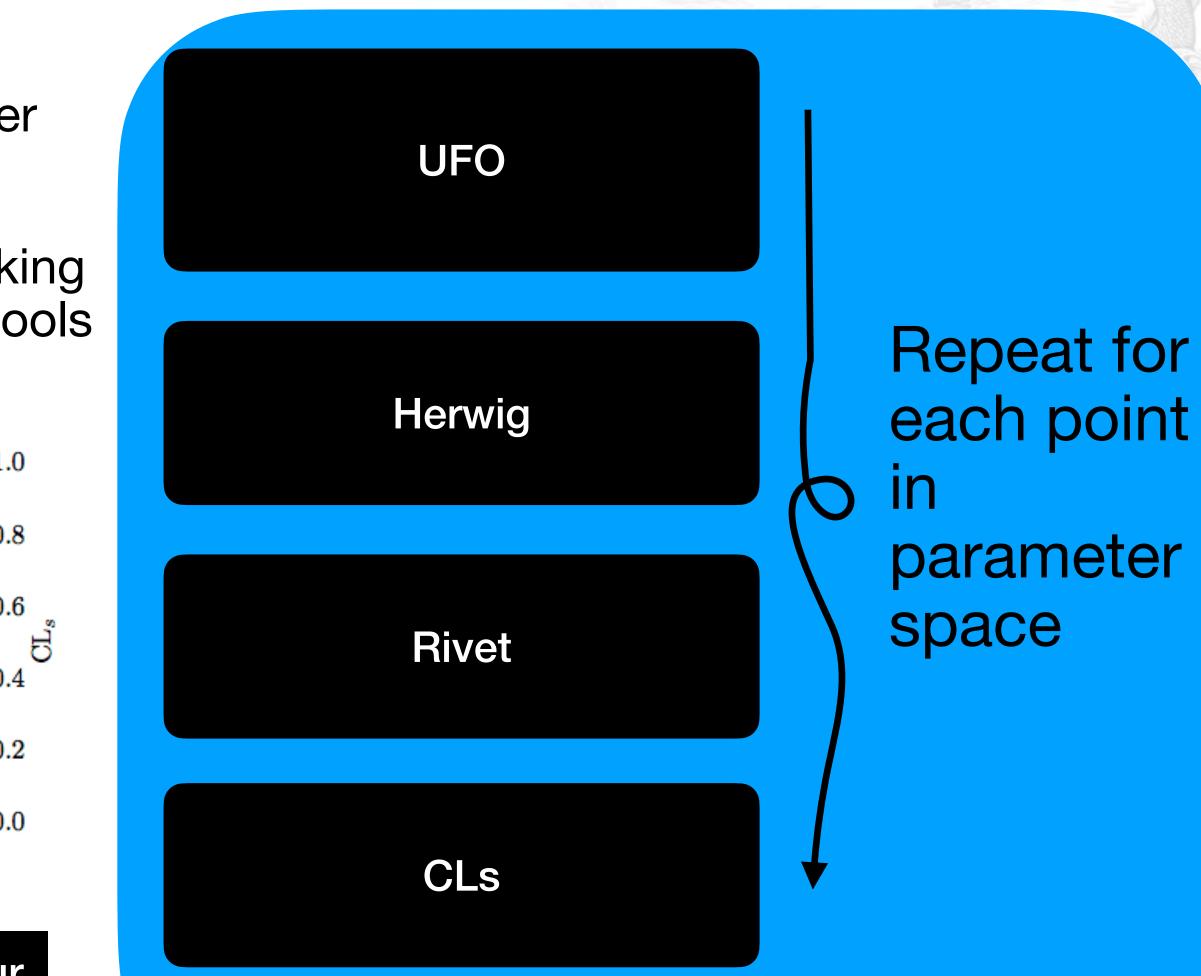

### Louie Corpe, UCL (I.corpe@ucl.ac.uk)

- CONTUR provides the book-keeping and steering machinery to repeat this process over a grid of parameter values
- Run grid for 7, 8, 13 TeV separately, then combine by taking most sensitive measurement from orthogonal analysis pools

### Abstract

Quark partners with non-chiral couplings appear in several extensions of the Standard Model. They may have non-trivial generational structure to their couplings, and may be produced either in pairs via the strong and EM interactions, or singly via the new couplings of the model. Their decays often produce heavy quarks and gauge bosons, which will contribute to a variety of already-measured "Standard Model" cross-sections at the LHC. We present a study of the sensitivity of such published LHC measurements to vector-like quarks, first comparing to limits already obtained from dedicated searches, and then broadening to some so-far unstudied parameter regions.

Louie Corpe, UCL (I.corpe@ucl.ac.uk)

LHC programme has mostly focused here since reduced  $\kappa$ dependence,

But singleproduction has rich phenomenology which we can probe with CONTUR!

LHC searches mostly focused on 3rd-gen, but 1st-gen has richer phenomenology due to valencequark-induced production

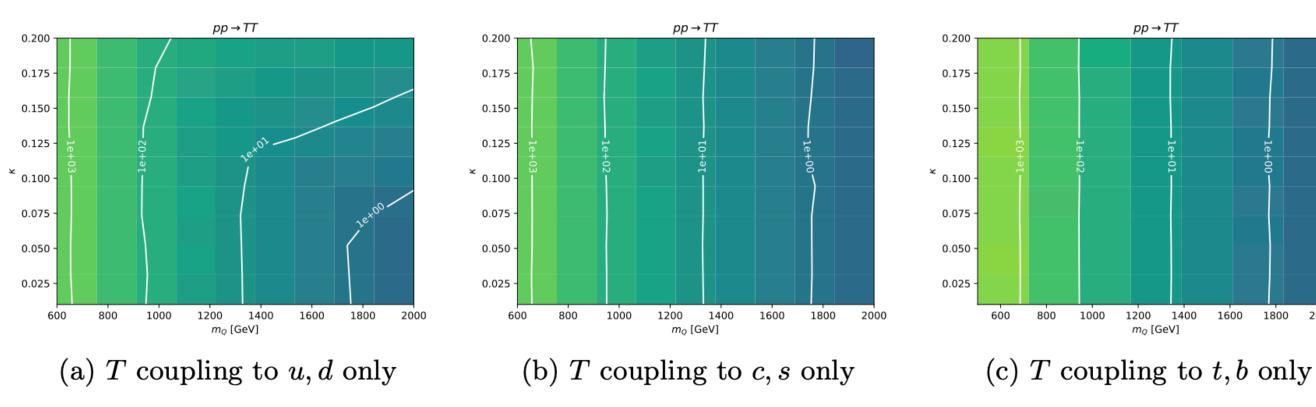

(i)

(h)

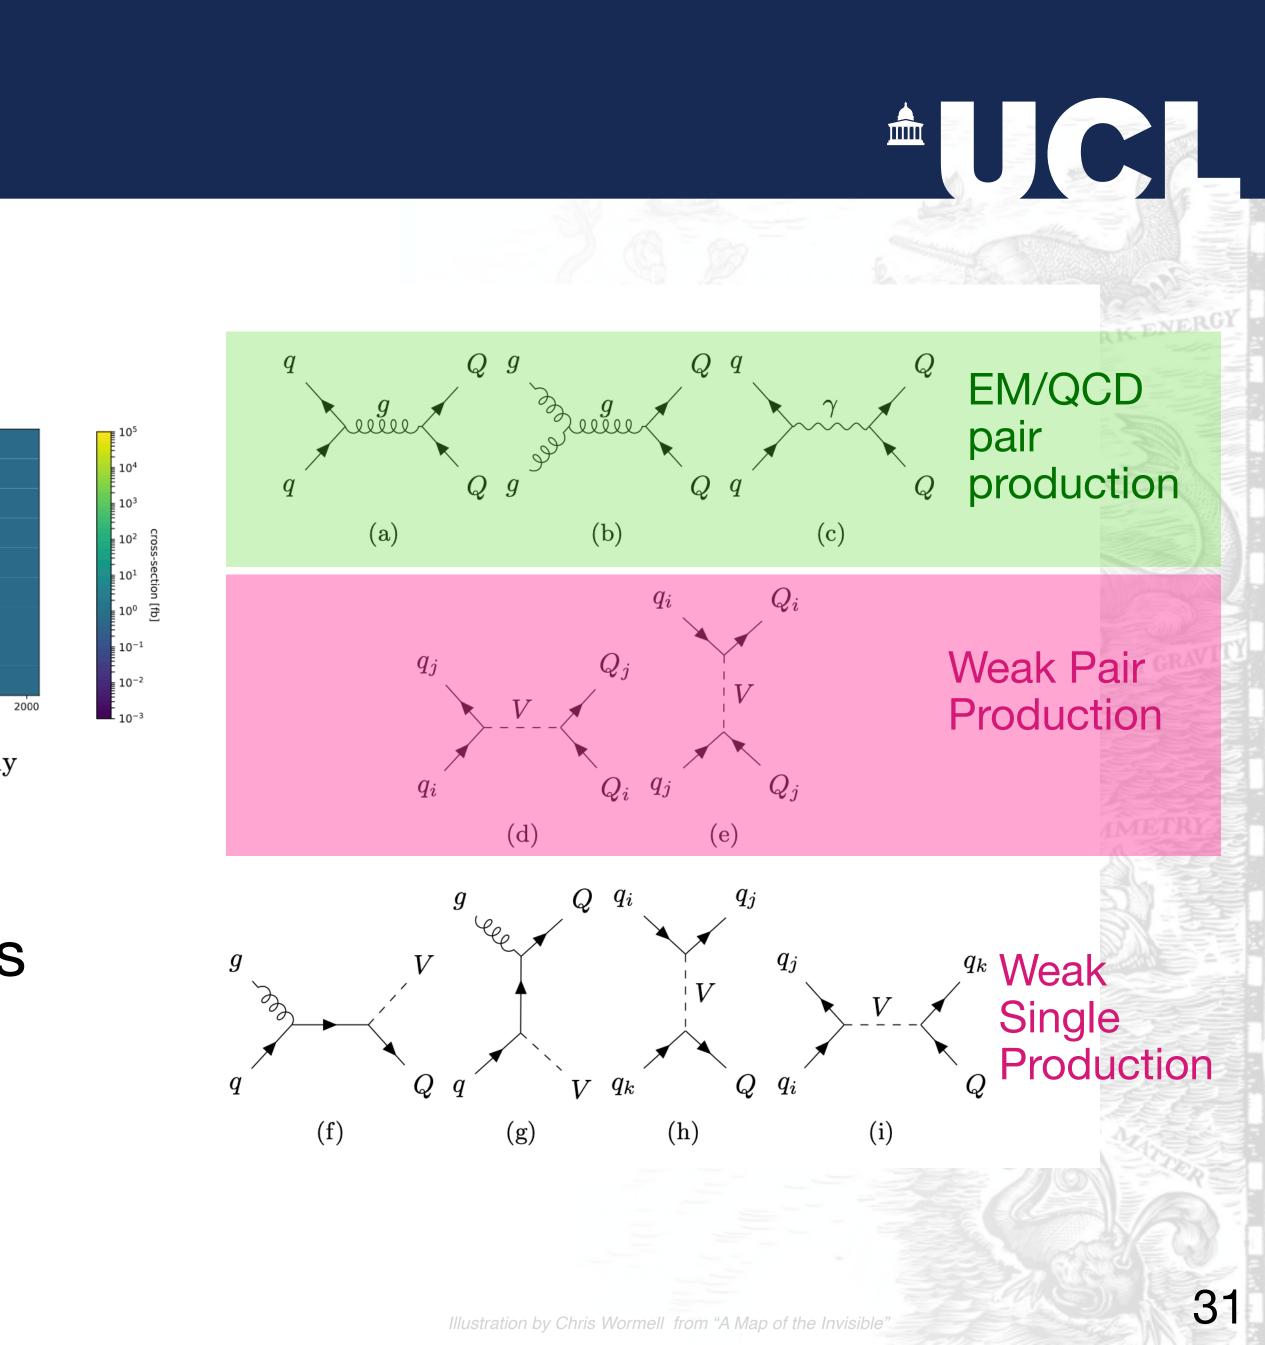

# Assuming $\xi$ such that W:Z:H=1:1:1

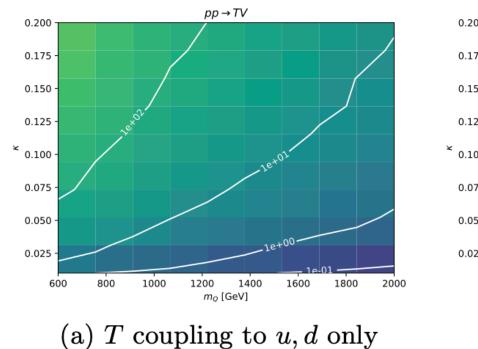

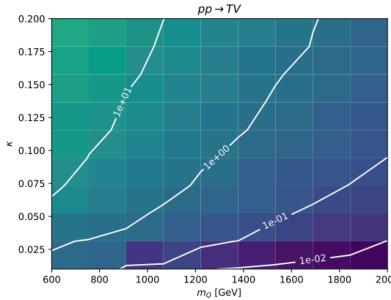

# 1st-gen couplings: even pair-production has $\kappa$ -dependence due to weak production initiated by valence quarks

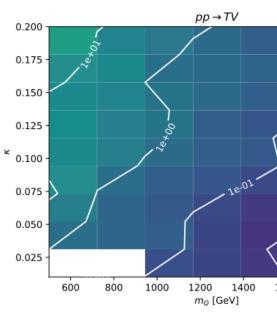

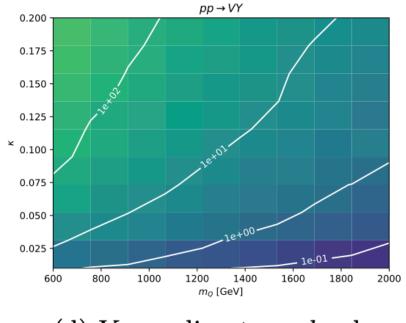

# Assuming $\xi$ such that W:Z:H=1:1:1

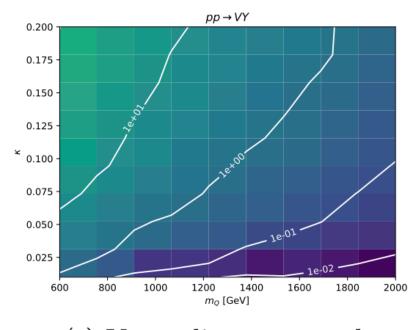

(b) T coupling to c, s only

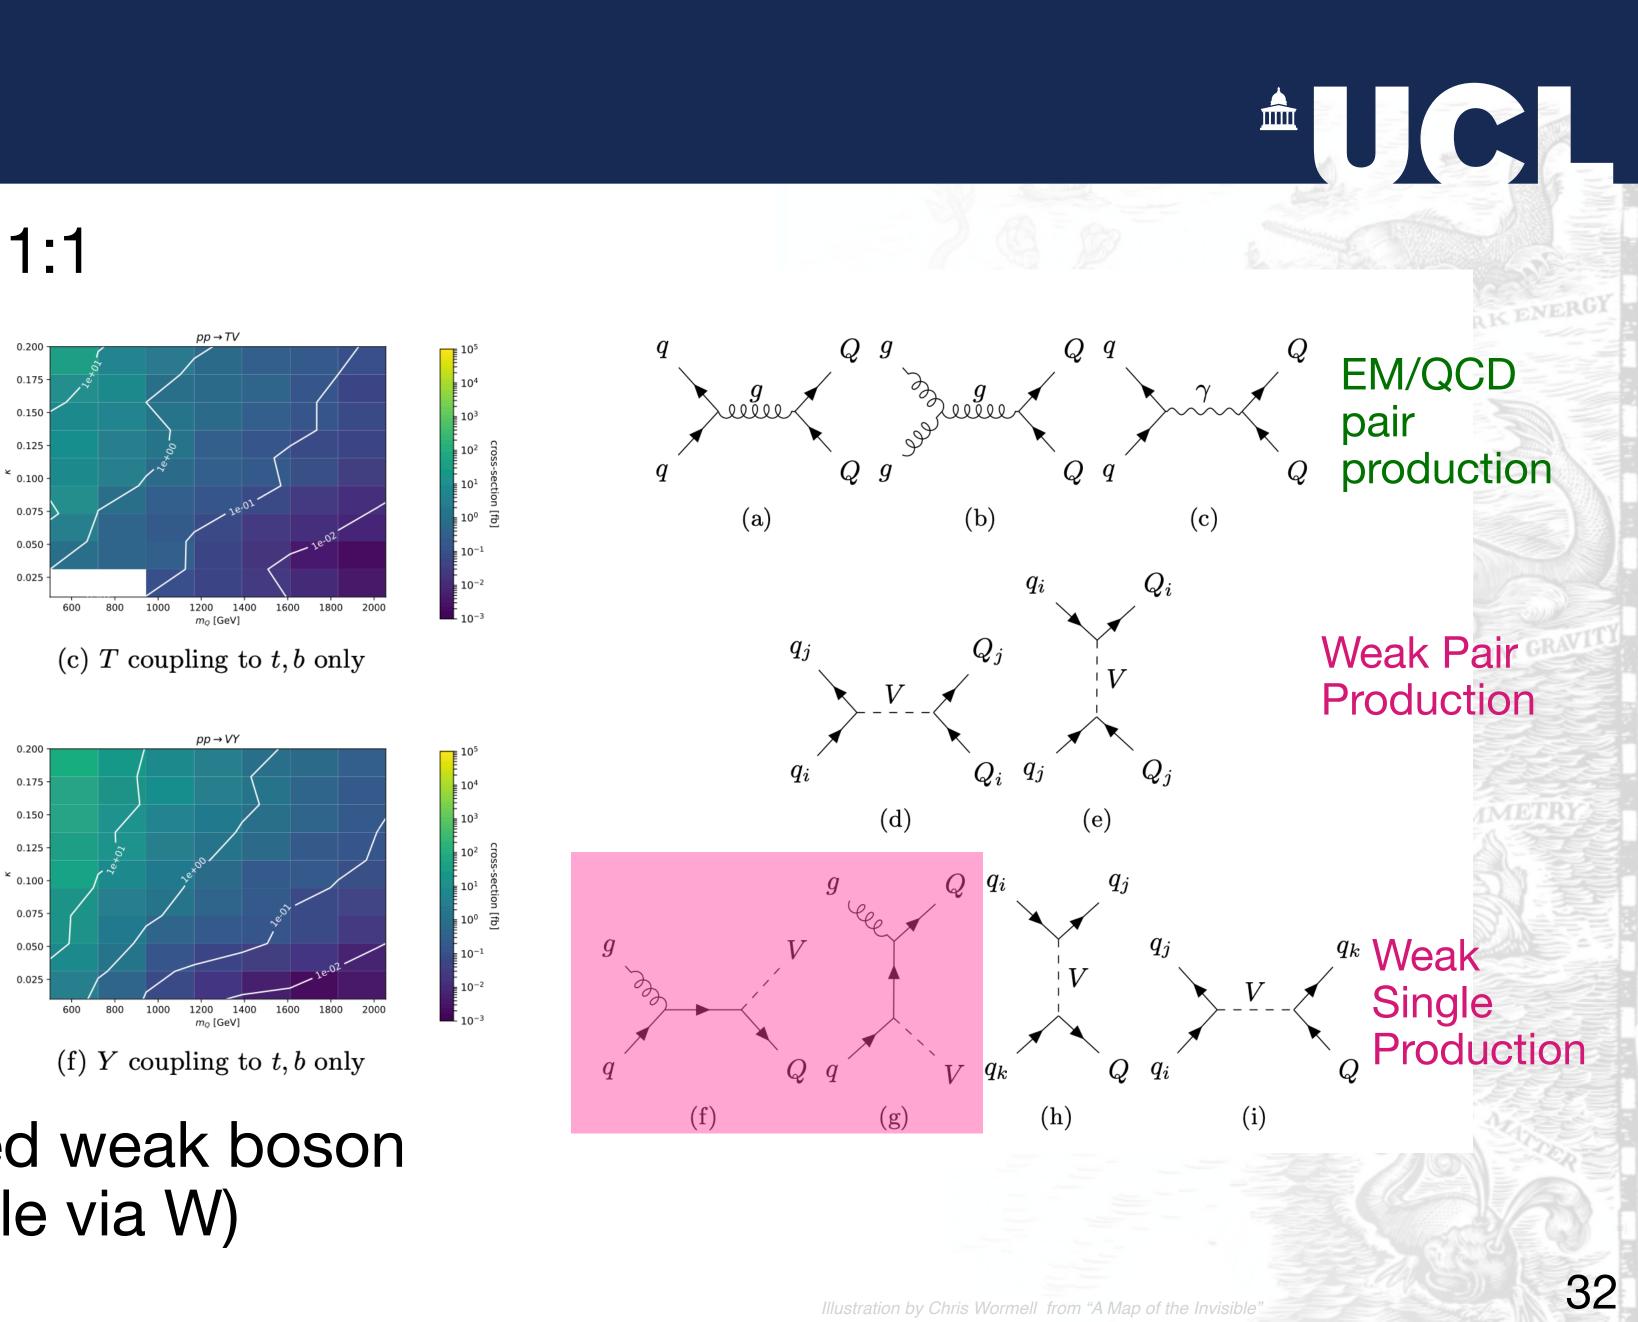

(d) Y coupling to u, d only

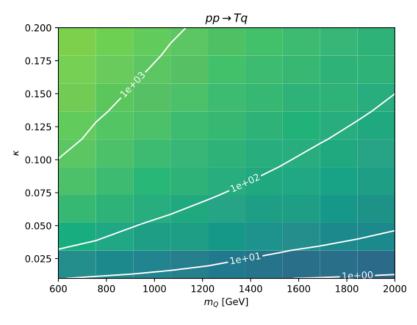

(e) Y coupling to c, s only

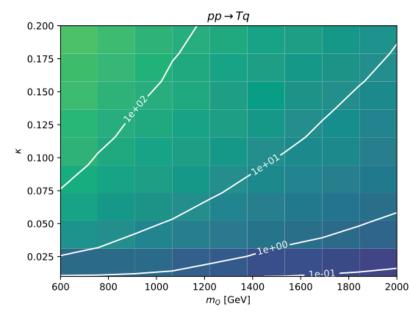

# VLQ production with associated weak boson (for X and Y, this is only possible via W)

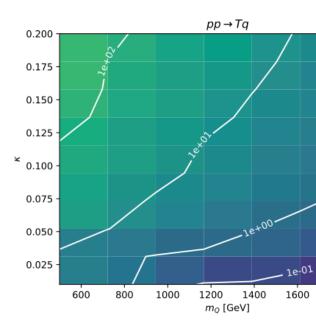

# Assuming $\xi$ such that W:Z:H=1:1:1

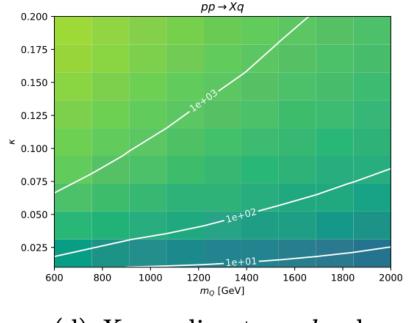

(a) T coupling to u, d only

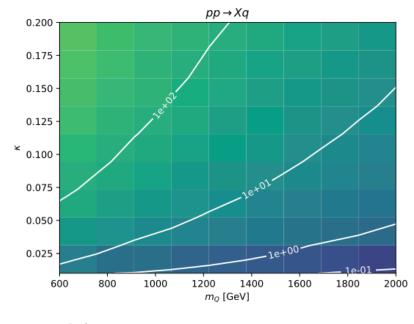

(b) T coupling to c, s only

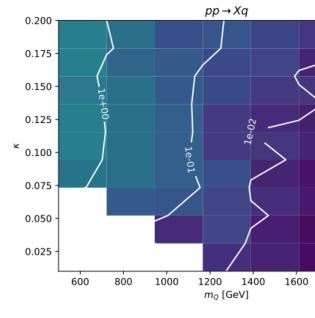

(d) X coupling to u, d only

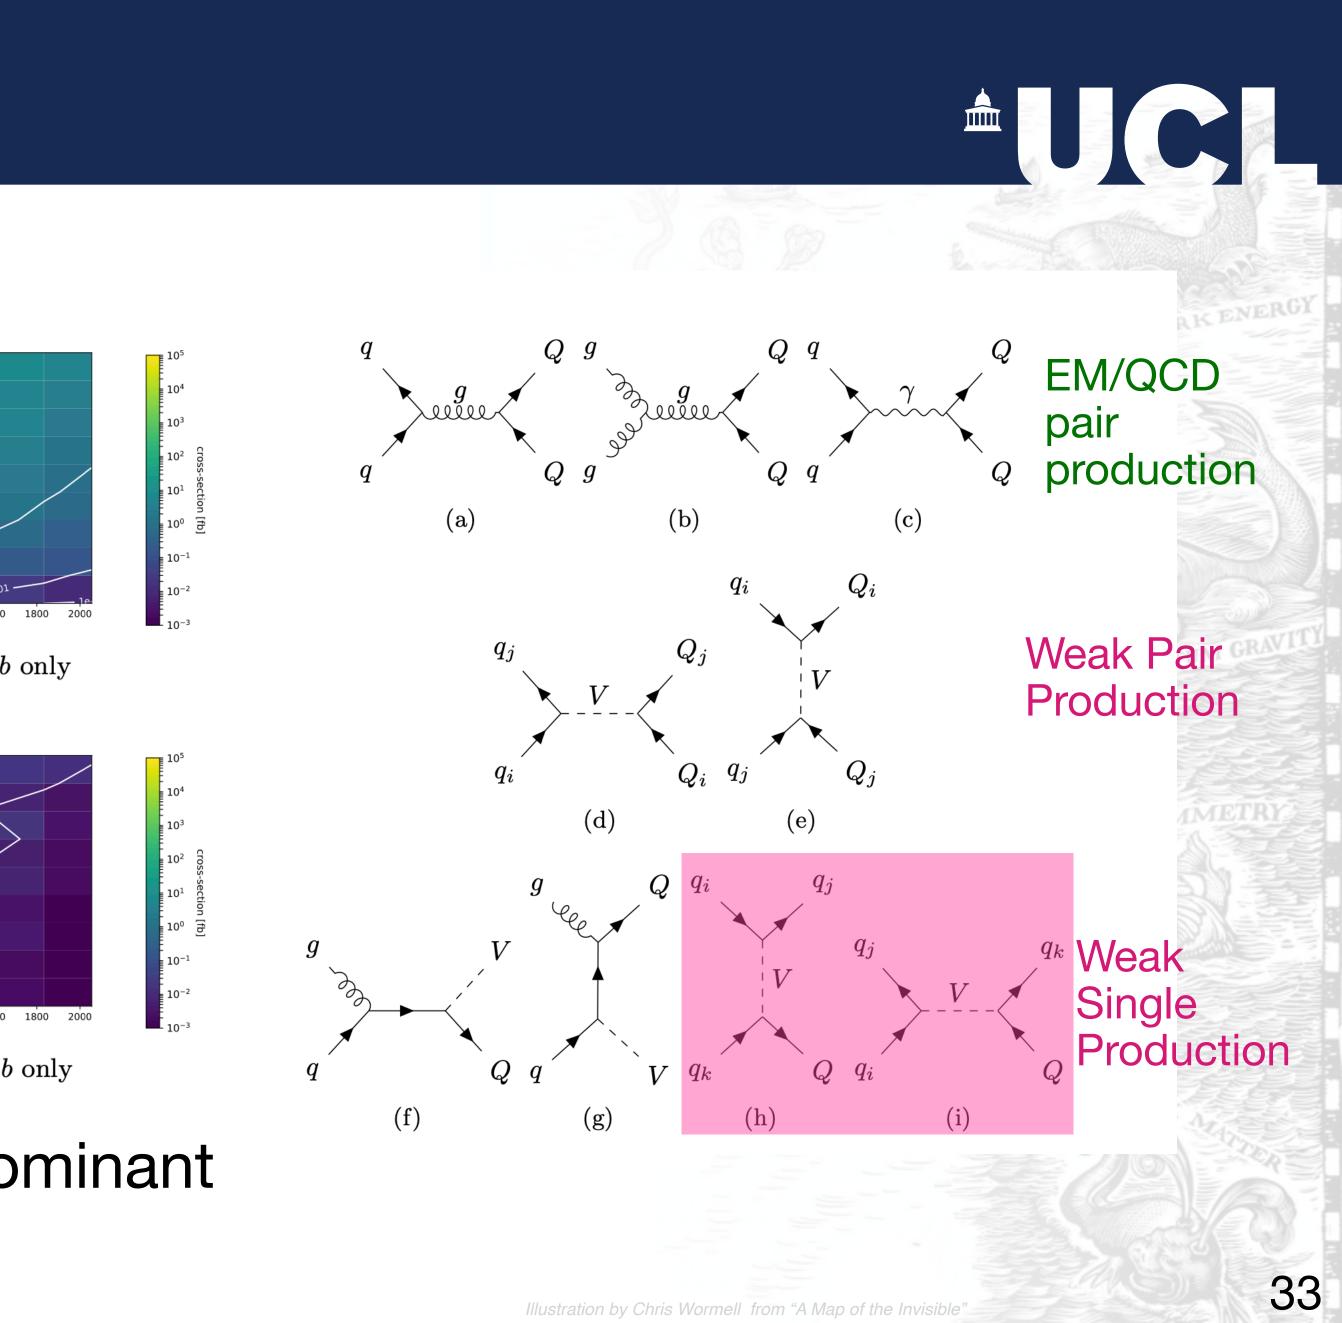

(e) X coupling to c, s only

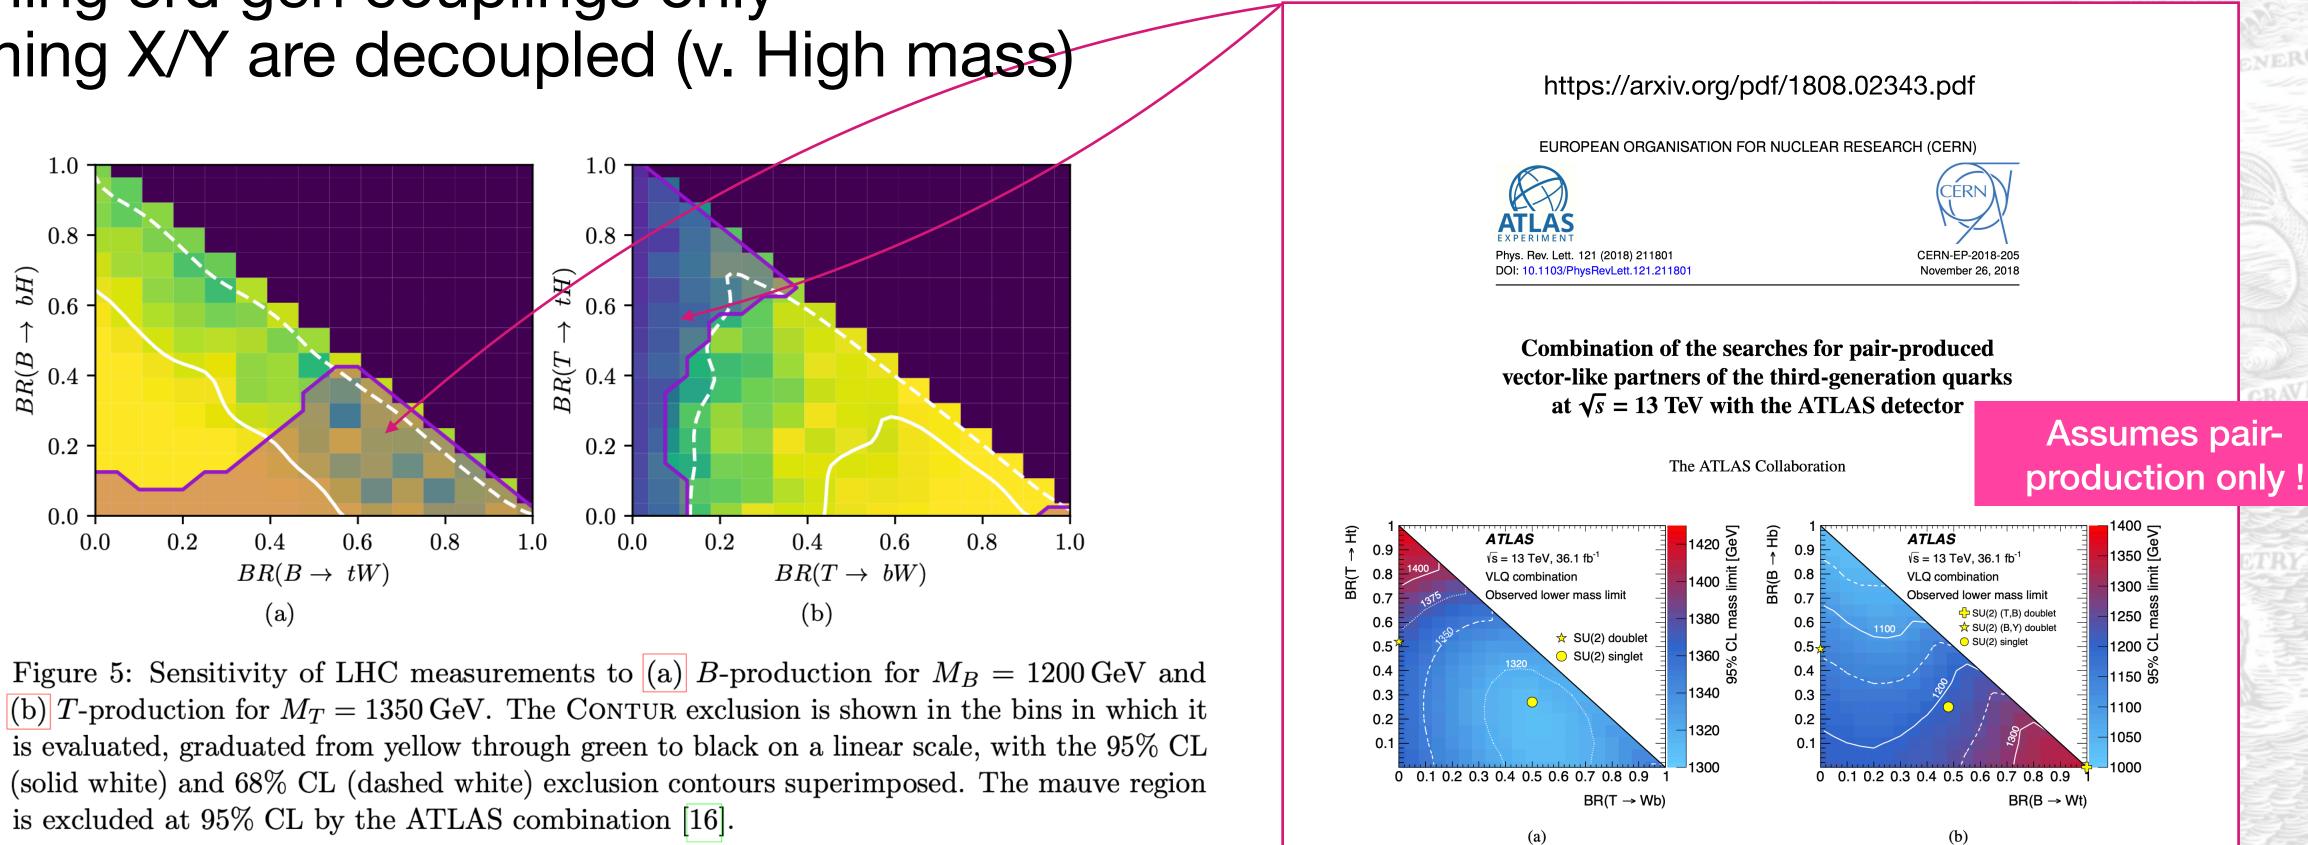

<sup>(</sup>f) X coupling to t, b only

# VLQ production with SM quark: can be dominant over pair-production in 1st-gen scenario!

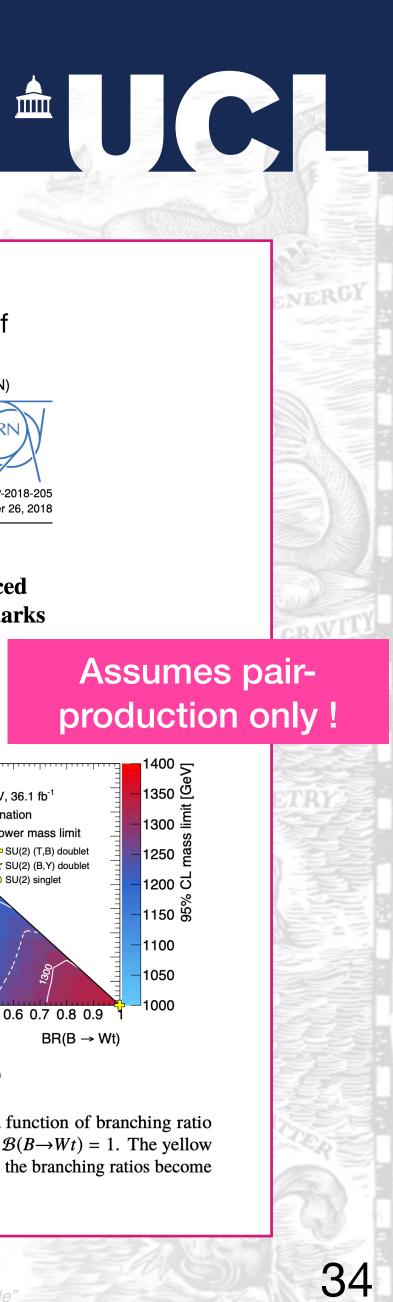

# Assuming 3rd gen couplings only Assuming X/Y are decoupled (v. High mass)

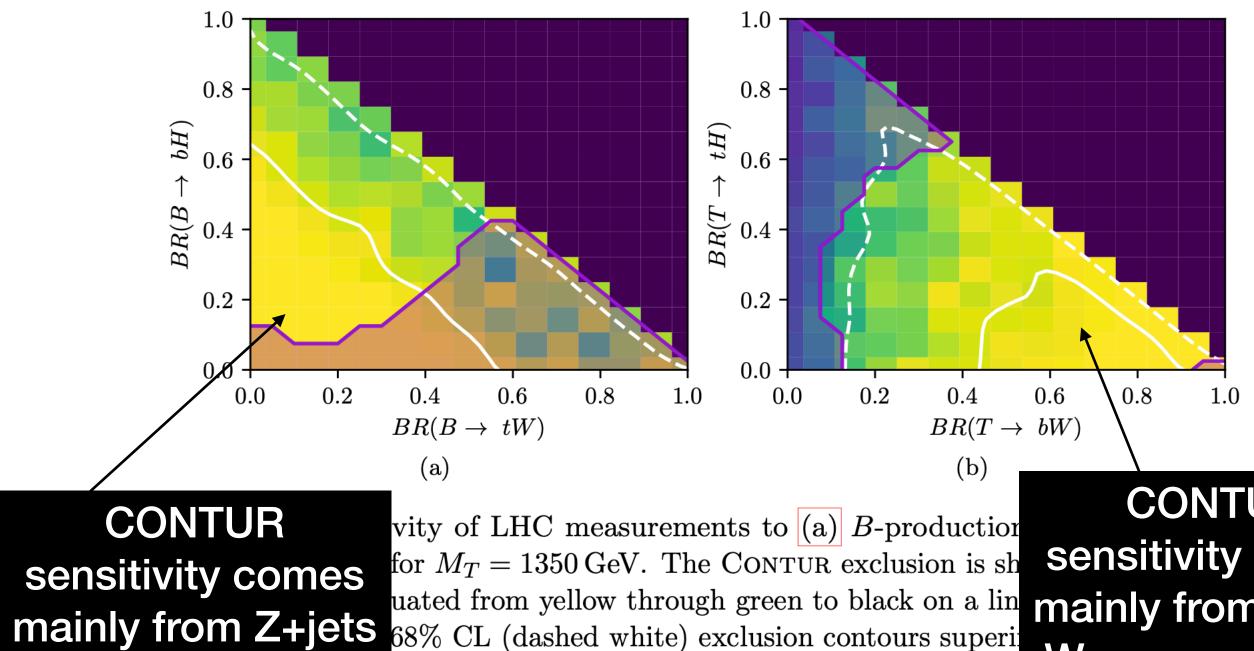

### Louie Corpe, UCL (I.corpe@ucl.ac.uk)

Figure 4: Observed lower limits at 95% CL on the mass of the (a) T and (b) B as a function of branching ratio assuming  $\mathcal{B}(T \to Ht) + \mathcal{B}(T \to Zt) + \mathcal{B}(T \to Wb) = 1$  and  $\mathcal{B}(B \to Hb) + \mathcal{B}(B \to Zb) + \mathcal{B}(B \to Wt) = 1$ . The yellow markers indicate the branching ratios for the SU(2) singlet and doublet scenarios where the branching ratios become approximately independent of the VLQ mass [8].

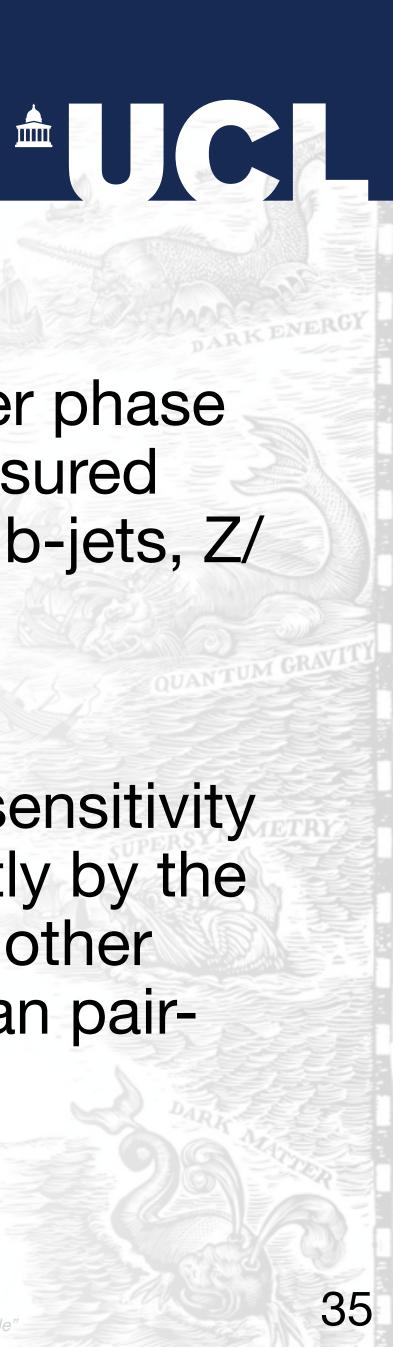

# Assuming 3rd gen couplings only Assuming X/Y are decoupled (v. High mass)

% CL by the ATLAS combination [16].

Louie Corpe, UCL (I.corpe@ucl.ac.uk)

measurements !

CONTUR sensitivity comes mainly from Top or W measurements

- VLQ decays may enter phase space of a many measured LHC cross-sections: b-jets, Z/ W+jets, dibosons, multipletons...
- Additional CONTUR sensitivity can be explained partly by the fact that we consider other production modes than pairproduction!

## Assuming 3rd gen couplings only Assuming B,T,X,Y have same mass

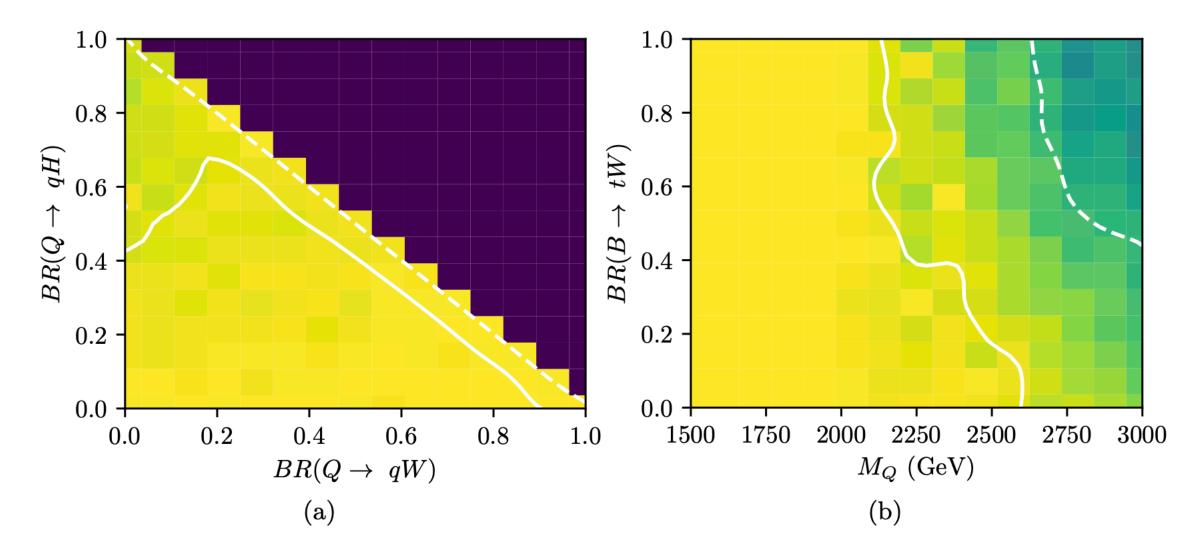

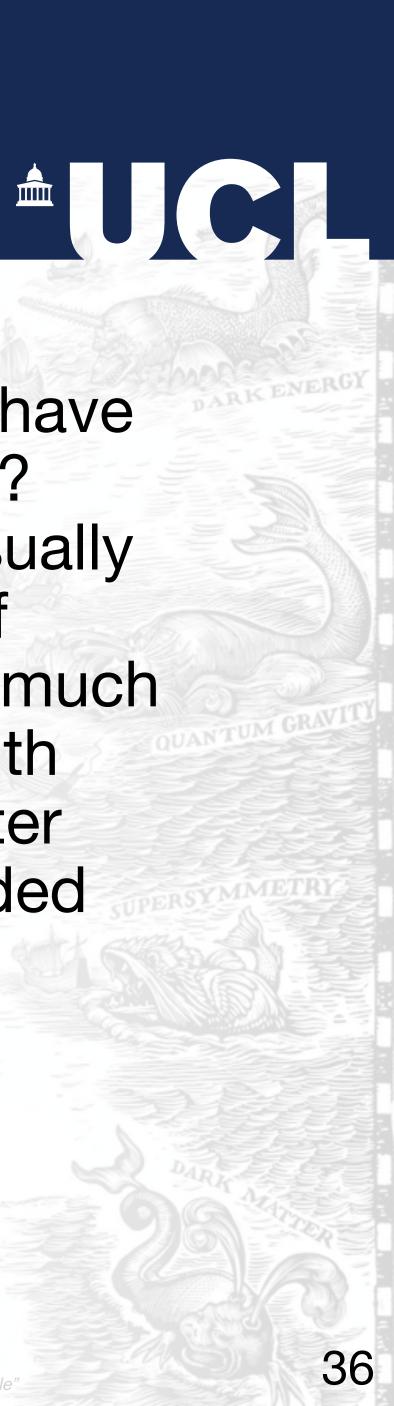

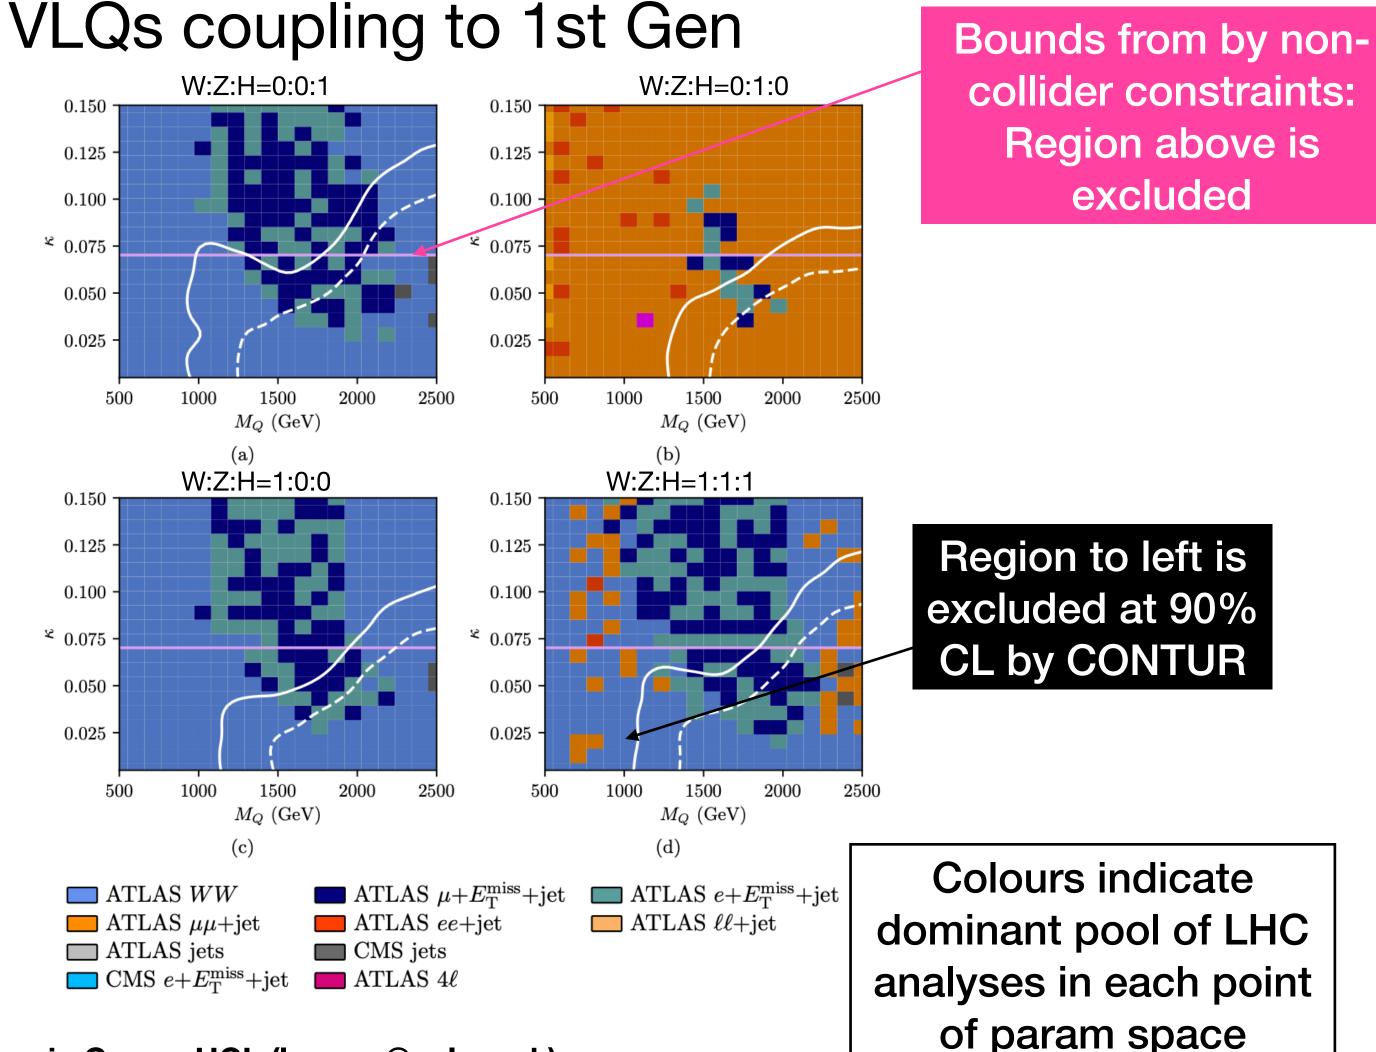

Figure 6: Sensitivity of LHC measurements to VLQ production when B, T, X, Y are degenerate in mass. The CONTUR exclusion is shown in the bins in which it is evaluated, graduated from yellow through green to black on a linear scale, with the 95% CL (solid white) and 68% CL (dashed white) exclusion contours superimposed. (a) Limit in the the branching fraction plane for  $M_Q = 2000 \text{ GeV}$ . (b) Limit in the plane of  $M_Q$  and  $BF(Q \to Wq) = 1 - BF(Q \to Zq)$ , for  $BF(Q \to Hq) = 0$ 

### Louie Corpe, UCL (I.corpe@ucl.ac.uk)

 Allowing all VLQs to have same mass (why not? Decoupling X/Y is usually done for simplicity of benchmarks) shows much greater sensitivity, with much of the parameter space already excluded

### Louie Corpe, UCL (I.corpe@ucl.ac.uk)

- Despite lack of dedicated searches, the 1stgeneration  $\kappa$ -m<sub>VLQ</sub> plane is largely excluded
- 'ATLAS WW' pool contains measurements in control regions of a search for leptoquarks. In many parts of plane, this is most sensitive analysis (unusual phase space probed!)
  - A strong argument for searches to make auxiliary particle-level measurements in their papers!
- The lep+MET+jet inclusions occur where pair production has died off but single-production retains appreciable cross-section
  - Sensitivity driven by control region measurements in an 8 TeV Wij measurement
- "One model's control region is another model's search region": model-independent measurements may be key to handling this conundrum !

Impact of QCD jet analyses also seen for higher masses (CMS 13 TeV jet mass, and ATLAS 13 TeV dijet and inclusive jet analyses)

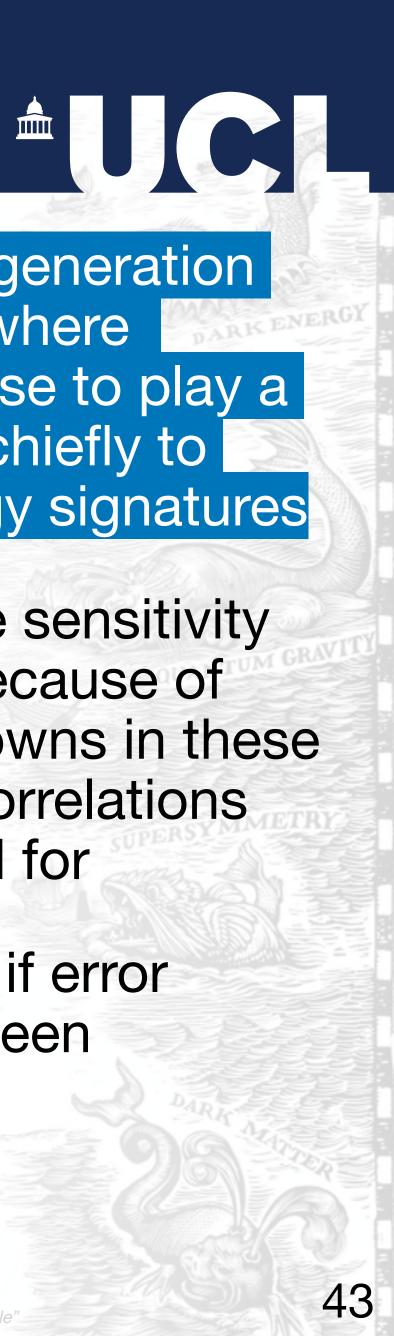

Louie Corpe, UCL (l.corpe@ucl.ac.uk)

Biggest difference with lower-generation scans is the WZH=010 case, where Z+jets-like measurements cease to play a leading role: VLQs will decay chiefly to tops, leading to missing-energy signatures

- Also notable is that a lot of the sensitivity in this scan is only possible because of published uncertainty breakdowns in these measurements, which allow correlations between bins to be accounted for
- Exclusion much more modest if error breakdowns would not have been published (see backup)!

of param space

# What about the (many) more realistic scenarios?

- During journal review, it has been pointed out to us that the scenario with all 4 extra VLQs is unrealistic — unlikely that new particles would form a quadruplet. Instead, we should consider:
  - Singlets: (B), (T)
  - Doublets: (BT), (XT), (TY)
  - Triplets: (BTX), (BTY)
- Each for 1st, 2nd, 3rd-generation couplings, and 4 benchmark W/ H/Z-coupling assumptions
- That's 7 multiplets, each with 3 generation-couplings, each with 4 W/H/Z-couplings, each with 300 points per scan, running 30,000 events at each point...
- Determining the constraints for this many scenarios in short order would normally take months... but can it be done with CONTUR?
- We wanted to use this challenge to put the CONTUR machinery to the test, and demonstrate the flexibility/speed of the method

Louie Corpe, UCL (l.corpe@ucl.ac.uk)

# What about the (many) more realistic scenarios?

49

- VLQ models, no just in a few benchmark scenarios...
  - Demonstrated speed of method
  - cases, made inroads into previously-open parameter space
- coded up in UFO format.
- The library of Rivet-preserved measurements just keeps growing. New HEPData entries are published

Using CONTUR, we have been able to to comprehensively probe a whole class of

Demonstrated complementarity of method to LHC search programme: in some

The same approach can be used for any model or class of models, so long as it's

measurements can be included in CONTUR as soon as their rivet routines and

# How to make your analysis CONTUR-friendly Some tips for experimentalists

TRA DIMENSION

- Measurements are the bread and butter of the CONTUR method. Here are things which make measurements easy to include:
  - Unfolded to particle-level
  - No model-dependent assumptions (Eg don't check flavours of neutrinos, no unnecessary background subtractions etc)
  - Preserved in Rivet routine, available at same time as arXiv submission (not years later! Some very powerful measurements are still without a Rivet routine, making them unusable. A waste of physics!)
  - HEPData published with breakdown of major uncertainties in each bin, in standard format (as labels, not a separate table)
  - Include best-available SM prediction as extra column in your **HEPData tables**

# https://www.hepdata.net/record/ins1720442

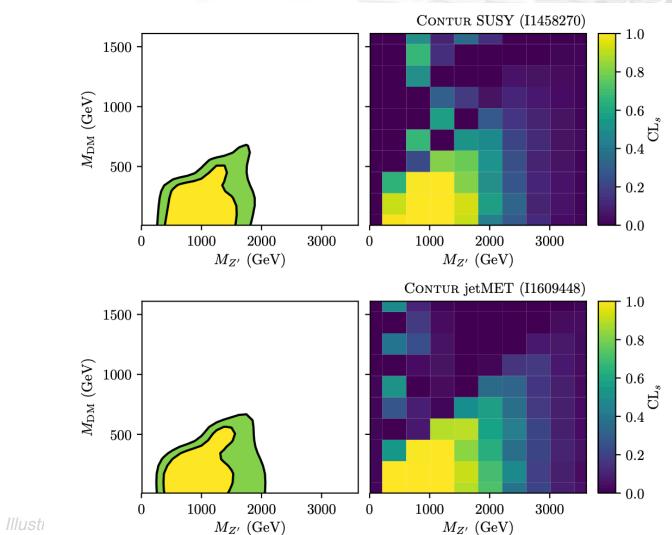

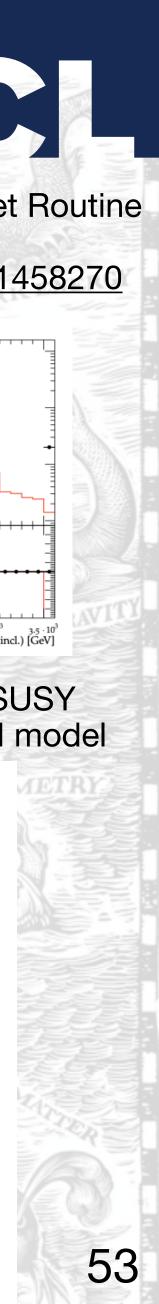

- CONTUR designed to work with particle-level measurements, but now also handles searches if preserved with a smeared Rivet routine (see Rivet smearing paper https://arxiv.org/abs/ <u>1910.01637</u>)
- For a 2HDM model, 3.2/fb squarks+gluinos (jet+MET) smeared Rivet routine was shown to exhibit similar sensitivity to 3.2/fb MET+jets measurement in Proceedings of Les Houches 2019 (https://arxiv.org/pdf/2002.12220.pdf)
- Control-region measurements from searches have great potential (see LQ CR measurement). Especially if uncertainty breakdown and SM background predictions are published on **HEPData**!
- CONTUR scans can help liberate search teams to cover the most challenging parts of model space, eg Long-lived Particles!

Example: 3.2/fb 13TeV squarks+gluinos has a Rivet Routine https://www.hepdata.net/record/ins1458270 https://rivet.hepforge.org/analyses/ATLAS 2016 I1458270

Example from LH19 proceedings: sensitivity to SUSY search and equivalent measurement for a 2HDM model

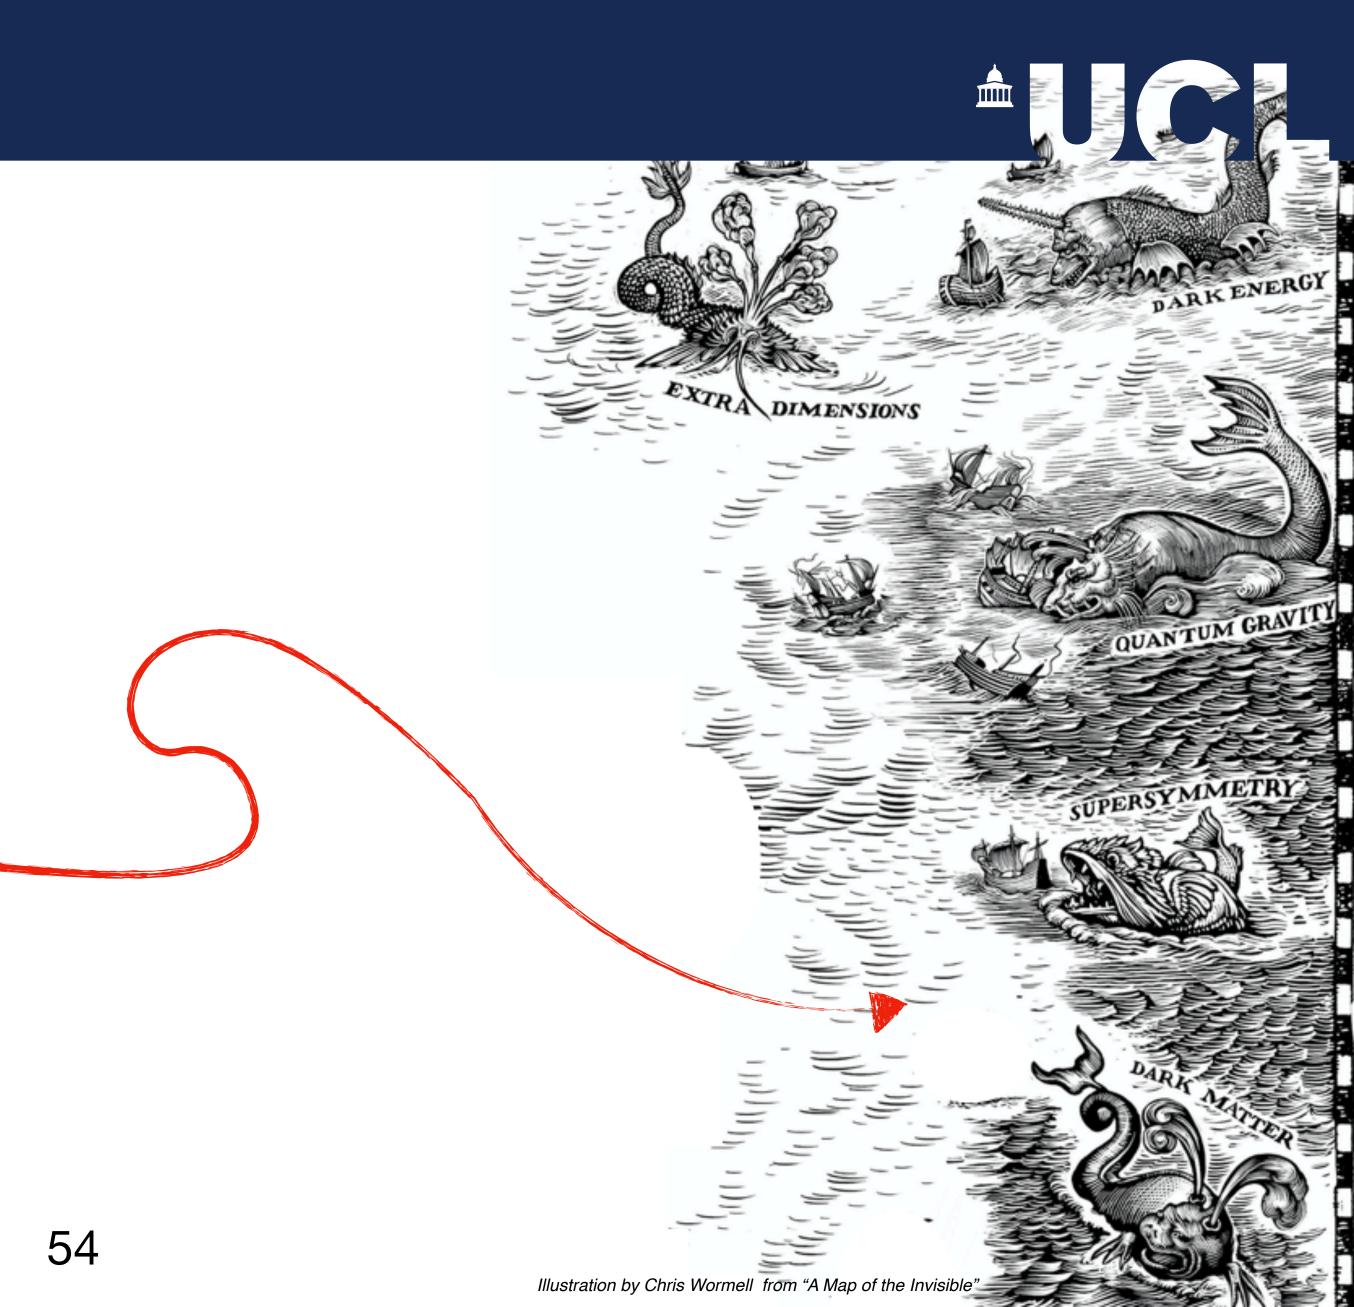

# **Conclusions and** Next steps

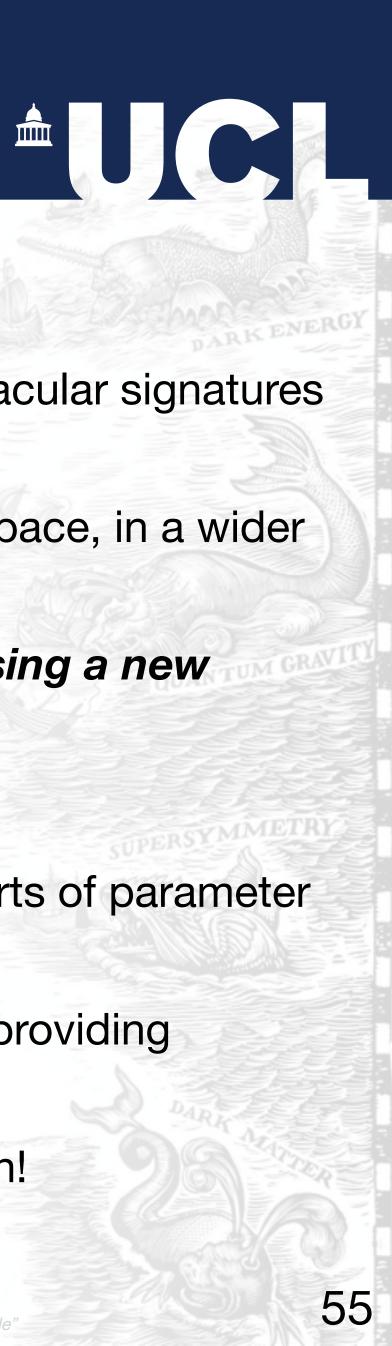

Louie Corpe, UCL (I.corpe@ucl.ac.uk)

- CONTUR allows study of existing LHC sensitivity to whole classes of models, here focusing on VLQs. Many other results available at <u>https://hepcedar.gitlab.io/contur-webpage/results/index.html</u>
- of model
- range of models than typically considered by search programme
- model or designing a search ?
  - Increasing amounts of data and pressure on computing resources makes this a compelling argument
- space (e.g. areas like long-lived particles, exotic signatures, etc...)
- Searches can also contribute to CONTUR, e.g. unfolded measurements in control (+ search ?) regions, or providing smeared Rivet routines
- CONTUR can be run by anyone! Please ask us about installing it on your cluster. User manual coming soon!
- Not discussed: CONTUR potential for analysis prototyping, upgrade studies, and more!

• Extract all 2->2 processes from Lagrangian: more comprehensive picture than just working on most spectacular signatures

• Measurements not explicitly designed for this purpose can exclude significant regions of VLQ parameter space, in a wider

# Should this sort of scan (which takes ~days on a cluster) be part of the 'due diligence' when proposing a new

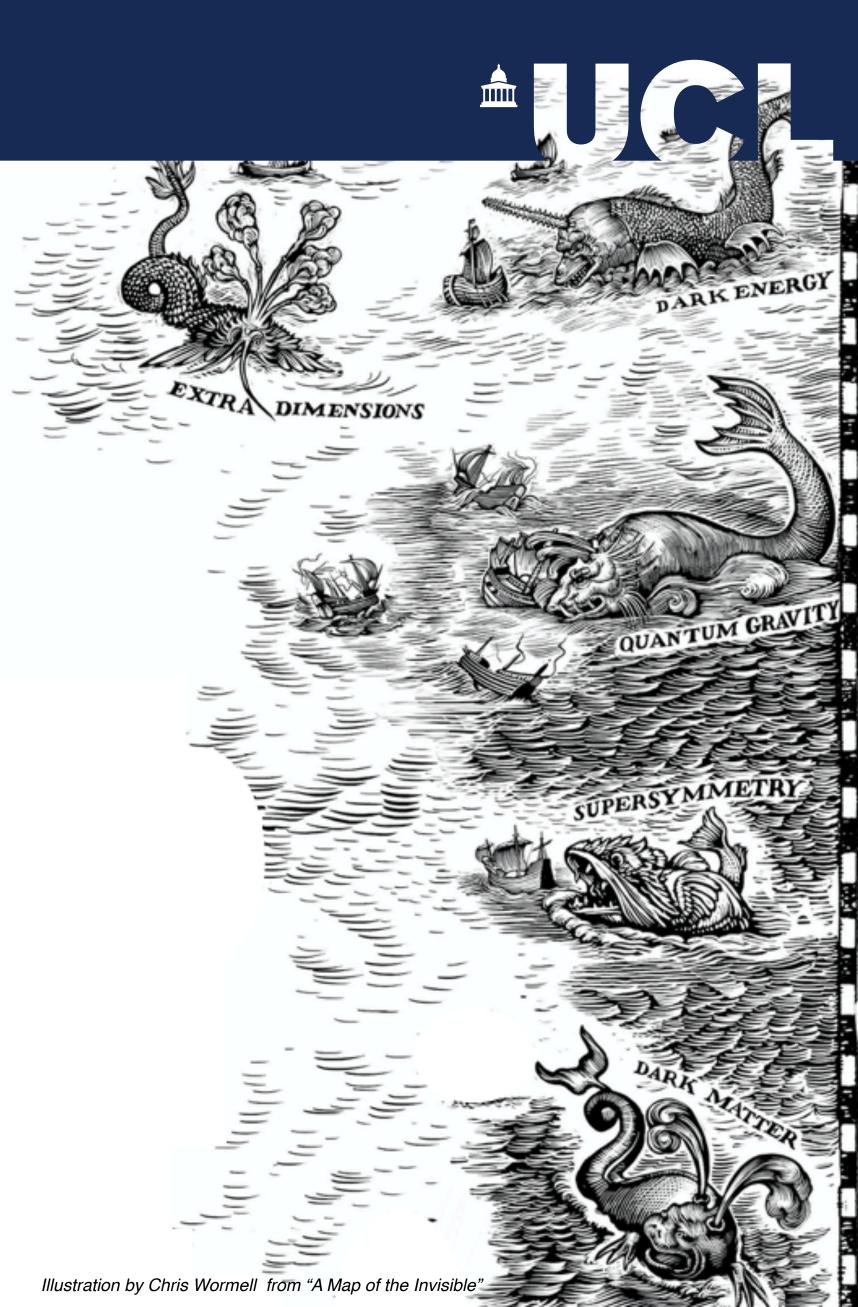

• Highly complementary approach to search programme, which is liberated to pin down the most elusive parts of parameter

# Thank you

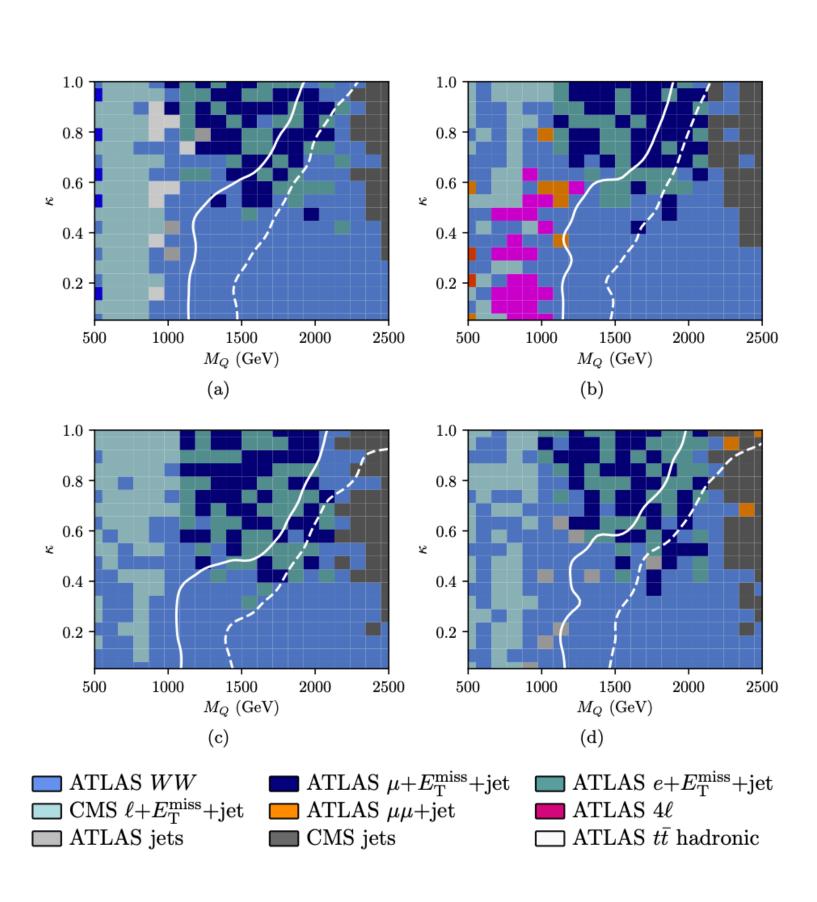

PS: ask us about CONTUR tutorials, running via docker, or installing it on your institute cluster!

### **B** Uncorrelated 3rd generation dominant-analyses maps

Louie Corpe, UCL (l.corpe@ucl.ac.uk)

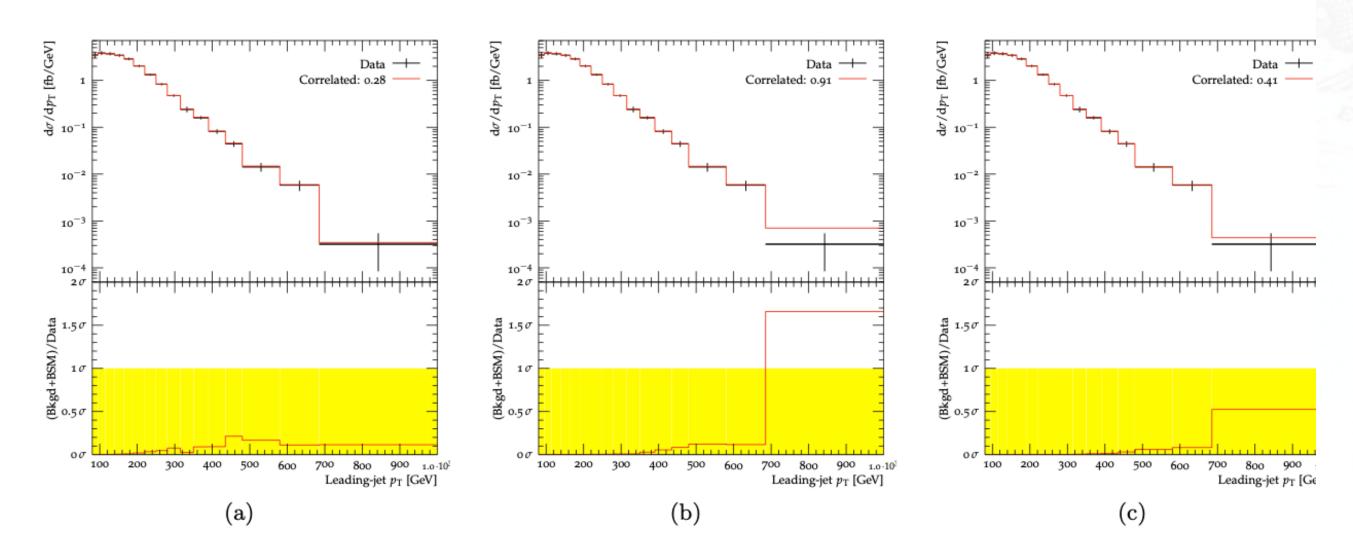

Figure 8: ATLAS 8 TeV  $W_{jj}$  forward-lepton control region leading-jet  $p_T$  distributions at the correlated systematic uncertainties.

three points on the 95% exclusion contour for W:Z:H = 1:0:0, respectively at  $M_Q$  values of (a) 1000 GeV, (b) 1750 GeV, and (c) 2250 GeV. The rise and subsidence of a 90% CL<sub>s</sub> exclusion from a single  $W_{jj}$  bin is seen as the contour passes from below 1 TeV to above 2 TeV. The black points are data, the red histogram is the VLQ contribution stacked on top of the data. In the lower insets, the ratio is shown and the yellow band indicates the significance, taking into account the statistical and systematic uncertainties on the data. The legend gives the exclusion (i.e. one minus the p-value) for that histogram after fitting nuisance parameters for

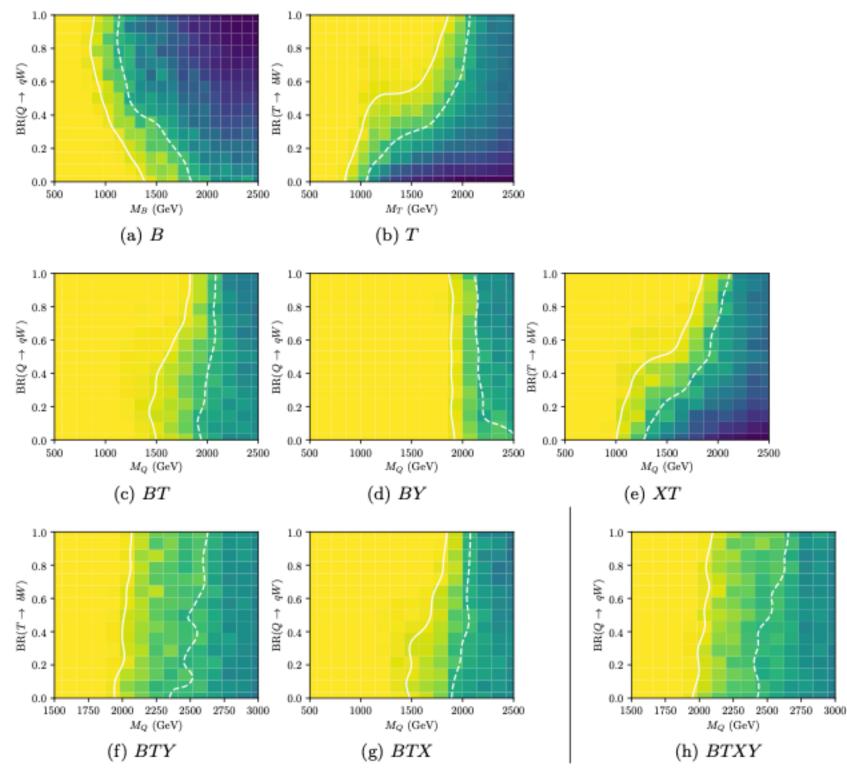

Figure 6: Sensitivity of LHC measurements to VLQ production when B, T, X, Y are degenerate in mass. The CONTUR exclusion is shown in the bins in which it is evaluated, graduated from yellow through green to black on a linear scale, with the 95% CL (solid white) and 68% CL (dashed white) exclusion contours superimposed. Limit in the plane of  $M_Q$  and BF $(Q \rightarrow Wq) = 1 - BF(Q \rightarrow Zq) - BF(Q \rightarrow Hq)$ , for BF $(Q \rightarrow Hq) = BF(Q \rightarrow Zq)$ .
