1/33

- $D^0(\bar{D}^0) \rightarrow K_S^0 \pi^+ \pi^-$ has 2 degrees of freedom typically describe phasespace with the 'Dalitz variables' $m_{\pm}^2 = (\rho_{K_S^0} + \rho_{\pi^{\pm}})^2$.
- We use the 'isobar' model to describe the complex valued amplitude of A_{D^0} :

$$A_{D^0}(\Phi) = \sum_r a_r A_r(\Phi) + \sum_{\mathrm{non-res}} A_{\mathrm{non-res}}(\Phi)$$

with couplings a_r to every resonance.

• If we assume no CP violation then $A_{\bar{D}^0}(m_+^2, m_-^2) = A_{D^0}^*(m_-^2, m_+^2).$

Strong Phase $\Delta \delta_D(\Phi)$ in $K_S^0 \pi^+ \pi^-$

Belle-BaBar 2018

Belle and BaBar (https://arxiv.org/abs/1804.06153v1), used 1.2*M* signal $D^0 \rightarrow K_S^0 \pi^+ \pi^-$ events from $B\bar{B}$ pairs.

Most accurate $D^0 \rightarrow K_S^0 \pi^+ \pi^-$ model to date.

CKM Measurements with $D^0(\bar{D}^0) \rightarrow K^0_S \pi^+ \pi^-$

 $D^0\bar{D}^0$ interfering terms lead to dependence on the relative phase between D^0 and $\bar{D}^0.$

Model Dependent Measurement of CKM parameters

- If the model for $B^{\pm} \rightarrow D(\rightarrow K_S^0 \pi^+ \pi^-) h^{\pm}$ is completely true, then $\sigma^{\text{syst}} = 0$ for the model.
- Problem is that the model for the decay might be wrong particularly with the $\Delta \delta_D(\Phi)$ - even if the magnitudes for D^0 and \overline{D}^0 are correct.
- From LHCb (2014) (arxiv.org/abs/1407.6211) measurement with $1 {\rm fb}^{-1}$, get $\gamma = (84^{+49}_{-42})^{\circ}$ including statistical and systematic uncertainties (would $\approx 16^{\circ}$ with the $9 {\rm fb}^{-1}$ data).
- σ^{syst} in this measurement is between 2% and 20% (depending on the parameter) of the σ^{stat} , this systematic is dominated by the choice of model for $D^0 \rightarrow K_5^0 \pi^+ \pi^-$.

- Systematics are clearly a big problem for these measurements.
- Modelling $\Delta \delta_D(\Phi)$ is likely the problem.
- Can 'measure' model $\Delta \delta_D(\Phi)$ from BESIII $\psi(3770) \rightarrow D^0 \overline{D}^0$ data, independent of the model https://arxiv.org/abs/2003.00091 by binning the strong phase into $\pm i = 1, 2, ..., N$ bins.

•
$$c_i + is_i = \frac{\int_i |A_{D^0}(\Phi)| |A_{Dzbar}(\Phi)| \exp(i\Delta\delta_D(\Phi)) d\Phi}{\sqrt{\int_i |A_{D^0}(\Phi)|^2 d\Phi \int_i |A_{\bar{D}^0}(\Phi)|^2 d\Phi}}$$

Binned Measurement of $\Delta \delta_D(\Phi)$

8/33

Binned Measurement of CKM parameters

- Then use results c_i, s_i from $\psi(3770)$ data as inputs and perform 'model-independent' measurements of CKM parameters by splitting the Dalitz plane in to $i = \pm 1, \pm 2, \pm N$ bins of $\Delta \delta_D$ using some binning scheme (built from a model).
- No more model systematics, but lose statistical precision due to binning and introduce systematics from the BESIII input.

•
$$\langle N_i^{B^-} \rangle \propto F_i + (x_-^2 + y_-^2) \overline{F}_i + 2\sqrt{F_i \overline{F}_i} (c_i x_- + s_i y_-)$$

•
$$\langle N_i^{B^+} \rangle \propto \overline{F}_i + (x_+^2 + y_+^2)F_i + 2\sqrt{F_i\overline{F}_i}(c_ix_+ - s_iy_+)$$

- The binned analysis at LHCb (https://arxiv.org/abs/1806.01202 with $9 \mathrm{fb}^{-1}$ obtained $\gamma = (68.7^{+5.2}_{-5.1})^{\circ}$.
- Initially thought that binning $\Delta \delta_D(\Phi)$ equally would yield best precision (smallest changes in $\Delta \delta_D(\Phi)$ in each bin.
- Further optimisations for the binning scheme have been performed - can get approximately 85% of the precision of the MD method https://arxiv.org/abs/1010.2817.

Quasi Model Independent measurement of $\Delta \delta_D$

- If $|A_D^0(\Phi)|$ is close to the 'truth' (i.e. that we trust the results for $|A_D^0(\Phi)|$ from the B-Factories).
- Belle-BaBar have no access to $\Delta \delta_D(\Phi)$ since only $D^0 \to K_S^0 \pi^+ \pi^-$ is studied.
- We attempt to 'correct' the $\Delta \delta_D(\Phi)$ that the Belle-BaBar model produces
- Replace $\Delta \delta_D(\Phi)$ with $\Delta \delta_D(\Phi) + f(\Phi|C)$, correcting the strong phase from a given model
- This is different from the 'Binned' method which calculates quantities that depend on $\Delta \delta_D(\Phi)$ in a model independent way
- We do not bin Φ at all we attempt to do a point by point correction to the strong phase in the two-dimensional Dalitz phase-space using correlated $D^0 \overline{D}^0$ prepared states (i.e. $\psi(3770) \rightarrow D^0 \overline{D}^0$ with at least one deccaying to $K_0^0 \pi^+ \pi^-$.

Quasi Model Independent measurement of $\Delta \delta_D$

f(Φ|C) is given as a two-dimensional polynomial in Dalitz space, Φ = (m²₊, m²₋):

$$f(\Phi|C) = \sum_{i=0}^{O} \sum_{j=0}^{O-i} C_{i,j} P_i(m_+^2) P_j(m_-^2)$$

• To preserve antisymmetry of $\Delta \delta_D(\Phi)$, we require $f(\Phi) = -f(\Phi^T)$,

• Can achieve this with transformation $\Phi = (m_+^2, m_-^2) \rightarrow \Phi' = (w_+(m_+^2, m_-^2), w_-(m_+^2, m_-^2)):$

$$w_+(m_+^2, m_-^2) = m_+^2 + m_-^2$$

 $w_-(m_+^2, m_-^2) = m_-^2 - m_+^2$

• Then these one-dimensional polynomials, $P_i(w_+)P_{2j+1}(w_-)$, i, j = 0, 1, 2...O build up the two-dimensional polynomial $f(\Phi|C)$ with $C_{i,2j+1}$ as the free parameters.

Quasi Model Independent measurement of $\Delta \delta_D$

- Begin with Dalitz
 Coordinates m²₊, m²₋.
- Right shows a polynomial with $C_{0,1} = 1$.

• Rotation of (m_+^2, m_-^2) to $(w_+(m_+^2, m_-^2), w_-(m_+^2, m_-^2))$ is one way to build polynomials that obey $f(m_+^2, m_-^2) = -f(m_-^2, m_+^2).$

Can stretch the input parameters into a square with:

$$w'_{-} = \frac{\alpha w_{-}}{bw_{+} + 1 - \varepsilon}$$

on right: $\alpha = 2, b = 1, \varepsilon = 0.01$

So we have the final form of our polynomial, $f(\Phi|C) = f(m_+^2, m_-^2|C)$:

$$f(m_{+}^{2}, m_{-}^{2}|C) = \sum_{i=0}^{O(C)} \sum_{j=0}^{O(C)-i} C_{i,2j+1} \\ \times P_{i}^{\text{legendre}}(w_{+}(m_{+}^{2}, m_{-}^{2})) \\ \times P_{2i+1}^{\text{legendre}}(w_{-}'(m_{+}^{2}, m_{-}^{2}))$$

with O(C) as our 'order', we chose Legendre polynomials for $P_i(x)$ since they gave smaller correlations of the polynomials we considered ('simple' $(P_i(x) = x^i)$ and 'Chebyshev').

• We used AmpGenhttps://github.com/GooFit/AmpGen to generate toy $\psi(3770) \rightarrow D^0 \overline{D}^0$ and $B^{\pm} \rightarrow DK^{\pm}$ samples.

Comparison of CKM precision between unbinned, QMI and binned measurements of CKM parameters

16 / 33

Comparison of CKM precision between unbinned, QMI and binned measurements of CKM parameters

17 / 33

• Define a 'Gaussian' bias to
$$\Delta \delta_D(\Phi)$$
,
 $f_G(\Phi|\mu_+, \mu_-, \sigma_+, \sigma_-, A, w_-^0)$
• $f(\Phi) = A \times \operatorname{erf}\left(\frac{w_-(m_+^2, m_-^2)}{w_-^0}\right) \times \begin{cases} G(m_+^2, \mu_+, \sigma_+)G(m_-^2, \mu_-, \sigma_-) & m_+^2 > m_-^2\\ G(m_-^2, \mu_+, \sigma_+)G(m_+^2, \mu_-, \sigma_-) & m_+^2 > m_-^2 \end{cases}$

•
$$G(x,\mu,\sigma) = \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$$

 erf(x) is the 'error' function used to smoothly vary from −1 to +1 over w_− < 0 to w_− > 0.

An extreme example of a bias to $\Delta \delta_D(\Phi)$

19 / 33

Recovery of $\Delta \delta_D(\Phi)$ with our method

Deciding on the order of the correcting polynomial in the QMI method

21/33

- Introduced a new method to measure $\Delta \delta_D(m_+^2, m_-^2)$.
- Method has much greater precision than the binned method.
- Method recovers from bias to $\Delta \delta_D(m_+^2, m_-^2)$ and therefore avoids large shifts in CKM parameters .
- $\sigma_{\rm MD}^{\rm stat} < \sigma_{\rm QMI}^{\rm stat} < \sigma_{\rm Binned}^{\rm stat}$.

Next...

- Write the method paper (In progress).
- Optimize implementation of method (lots of thanks to Tim Evans for creating and supporting AmpGen).
- Actually use the method in a measurement with data.
