Outline

1. Introduction

1.1. What is DAQ?

1.2. System architecture

2. Basic DAQ concepts

2.1. Digitization, Latency

2.2. Deadtime, Busy, Backpressure

2.3. De-randomization

3. Scaling up

3.1. Readout and Event Building

3.2. Buses vs Network

4. DAQ challenges at the LHC and beyond

What is DAQ?

[Wikipedia]

Data **A**c**Q**uisition (**DAQ**) is

- the process of **sampling signals**
- that **measure** real world physical conditions
- and **converting** the resulting samples **into digital** numeric values that can be manipulated by a computer

Ingredients:

- **Sensors**: convert physical quantities to electrical signals
- **Analog-to-digital converters**: convert conditioned sensor signals to digital values
- **Processing** and **storage** elements

What is DAQ?

[Real life]

DAQ is an **heterogeneous** field (*a.k.a. dark arts*)

- with boundaries not well defined

An **alchemy** of

- physics
- electronics
- computer science
- hacking
- networking
- experience

Where money and manpower matter as well

DAQ duties

Gather data produced by detectors

- **Readout**

Form complete events

- **Data Collection** and **Event Building**

Possibly feed extra processing levels

Store event data

- **Data Logging**

} **Data Flow**

Manage operations

- **Control**, **Configuration**, **Monitoring**

Interlude: data vs *interesting* data

Interesting physics data typically a small fraction of sampled signals

- **really, Really, REALLY** small

Logging all recorded data is unpractical (and costly)

- sometimes technically unfeasible

Online data reduction before logging becomes imperative

That's the job of the **Trigger**!

- DAQ and Trigger deeply entwined
  - often referred as TDAQ

Trigger Lecture - Dr. Julie Kirk

- All you wanted to know about trigger and never dared to ask, today, after coffee break! ☕

Trigger in a nutshell

Selects interesting events **AND** rejects boring ones, *in real time*

- **Selective:** efficient for “signal” and resistant to “background”
- **Simple** and **robust:** Must be predictable at all times!
- **Fast:** Late is no better than never

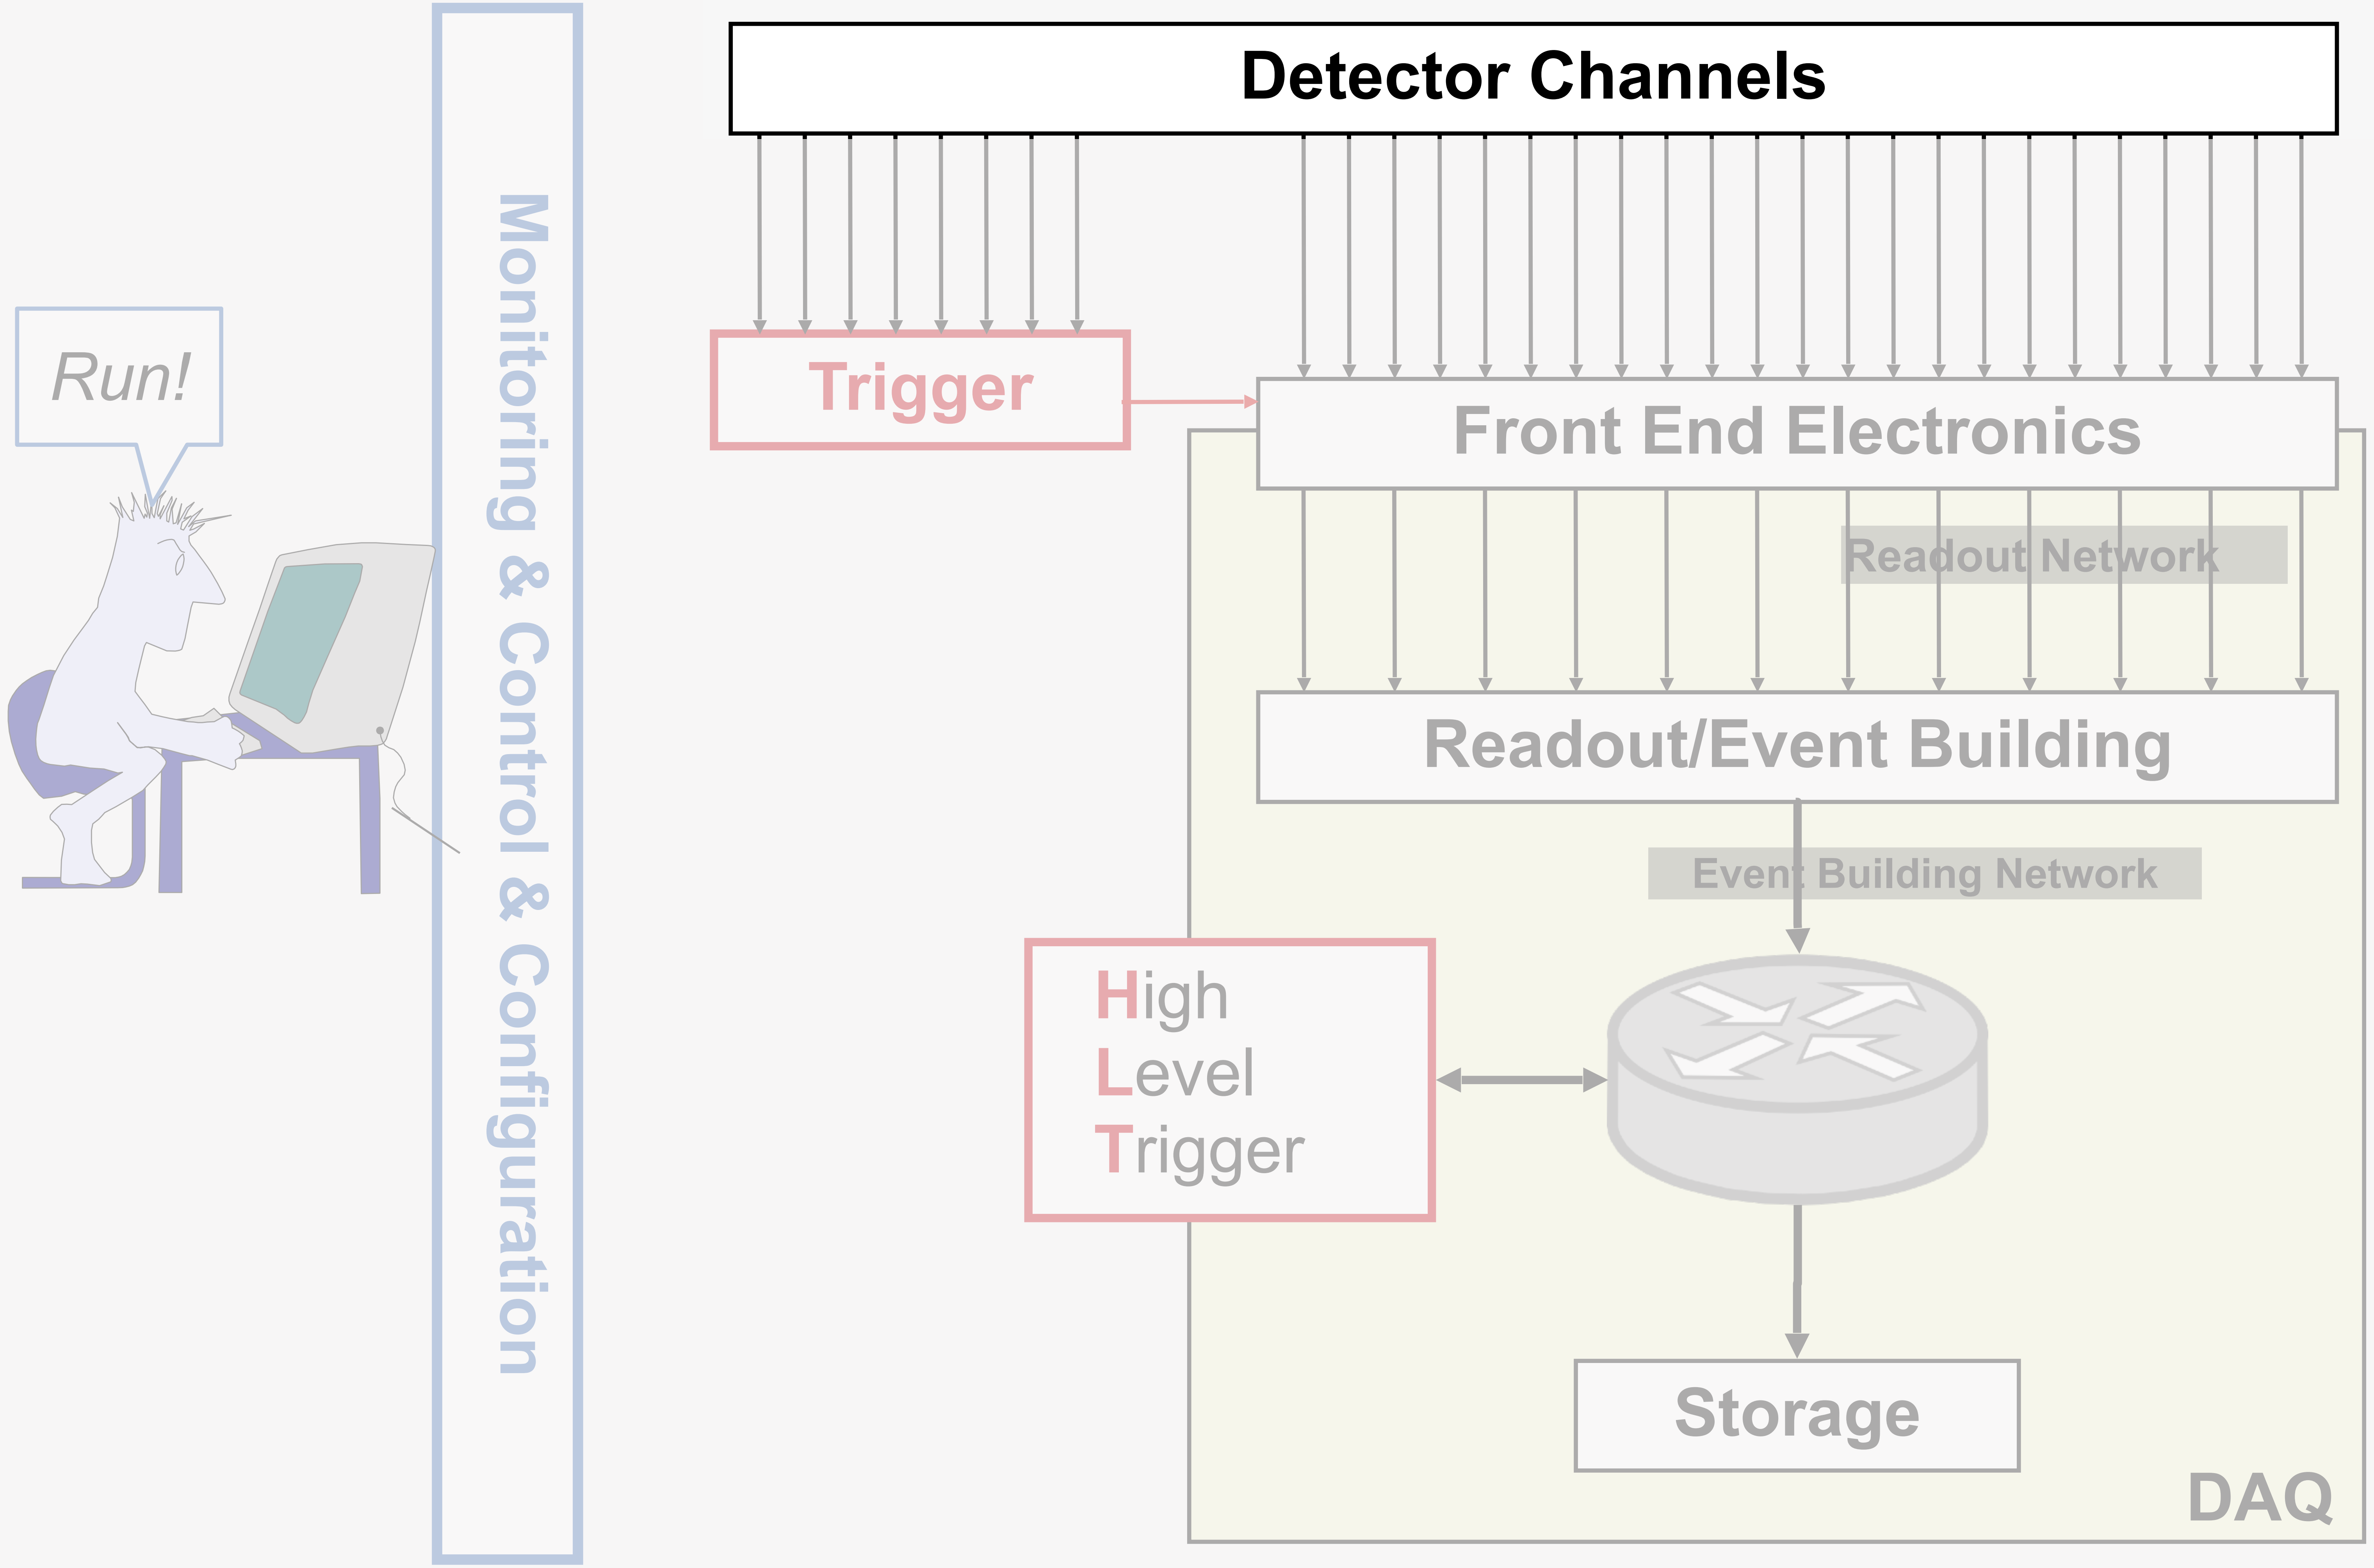
With minimal *controlled* **latency**

- time it takes to form and distribute its decision

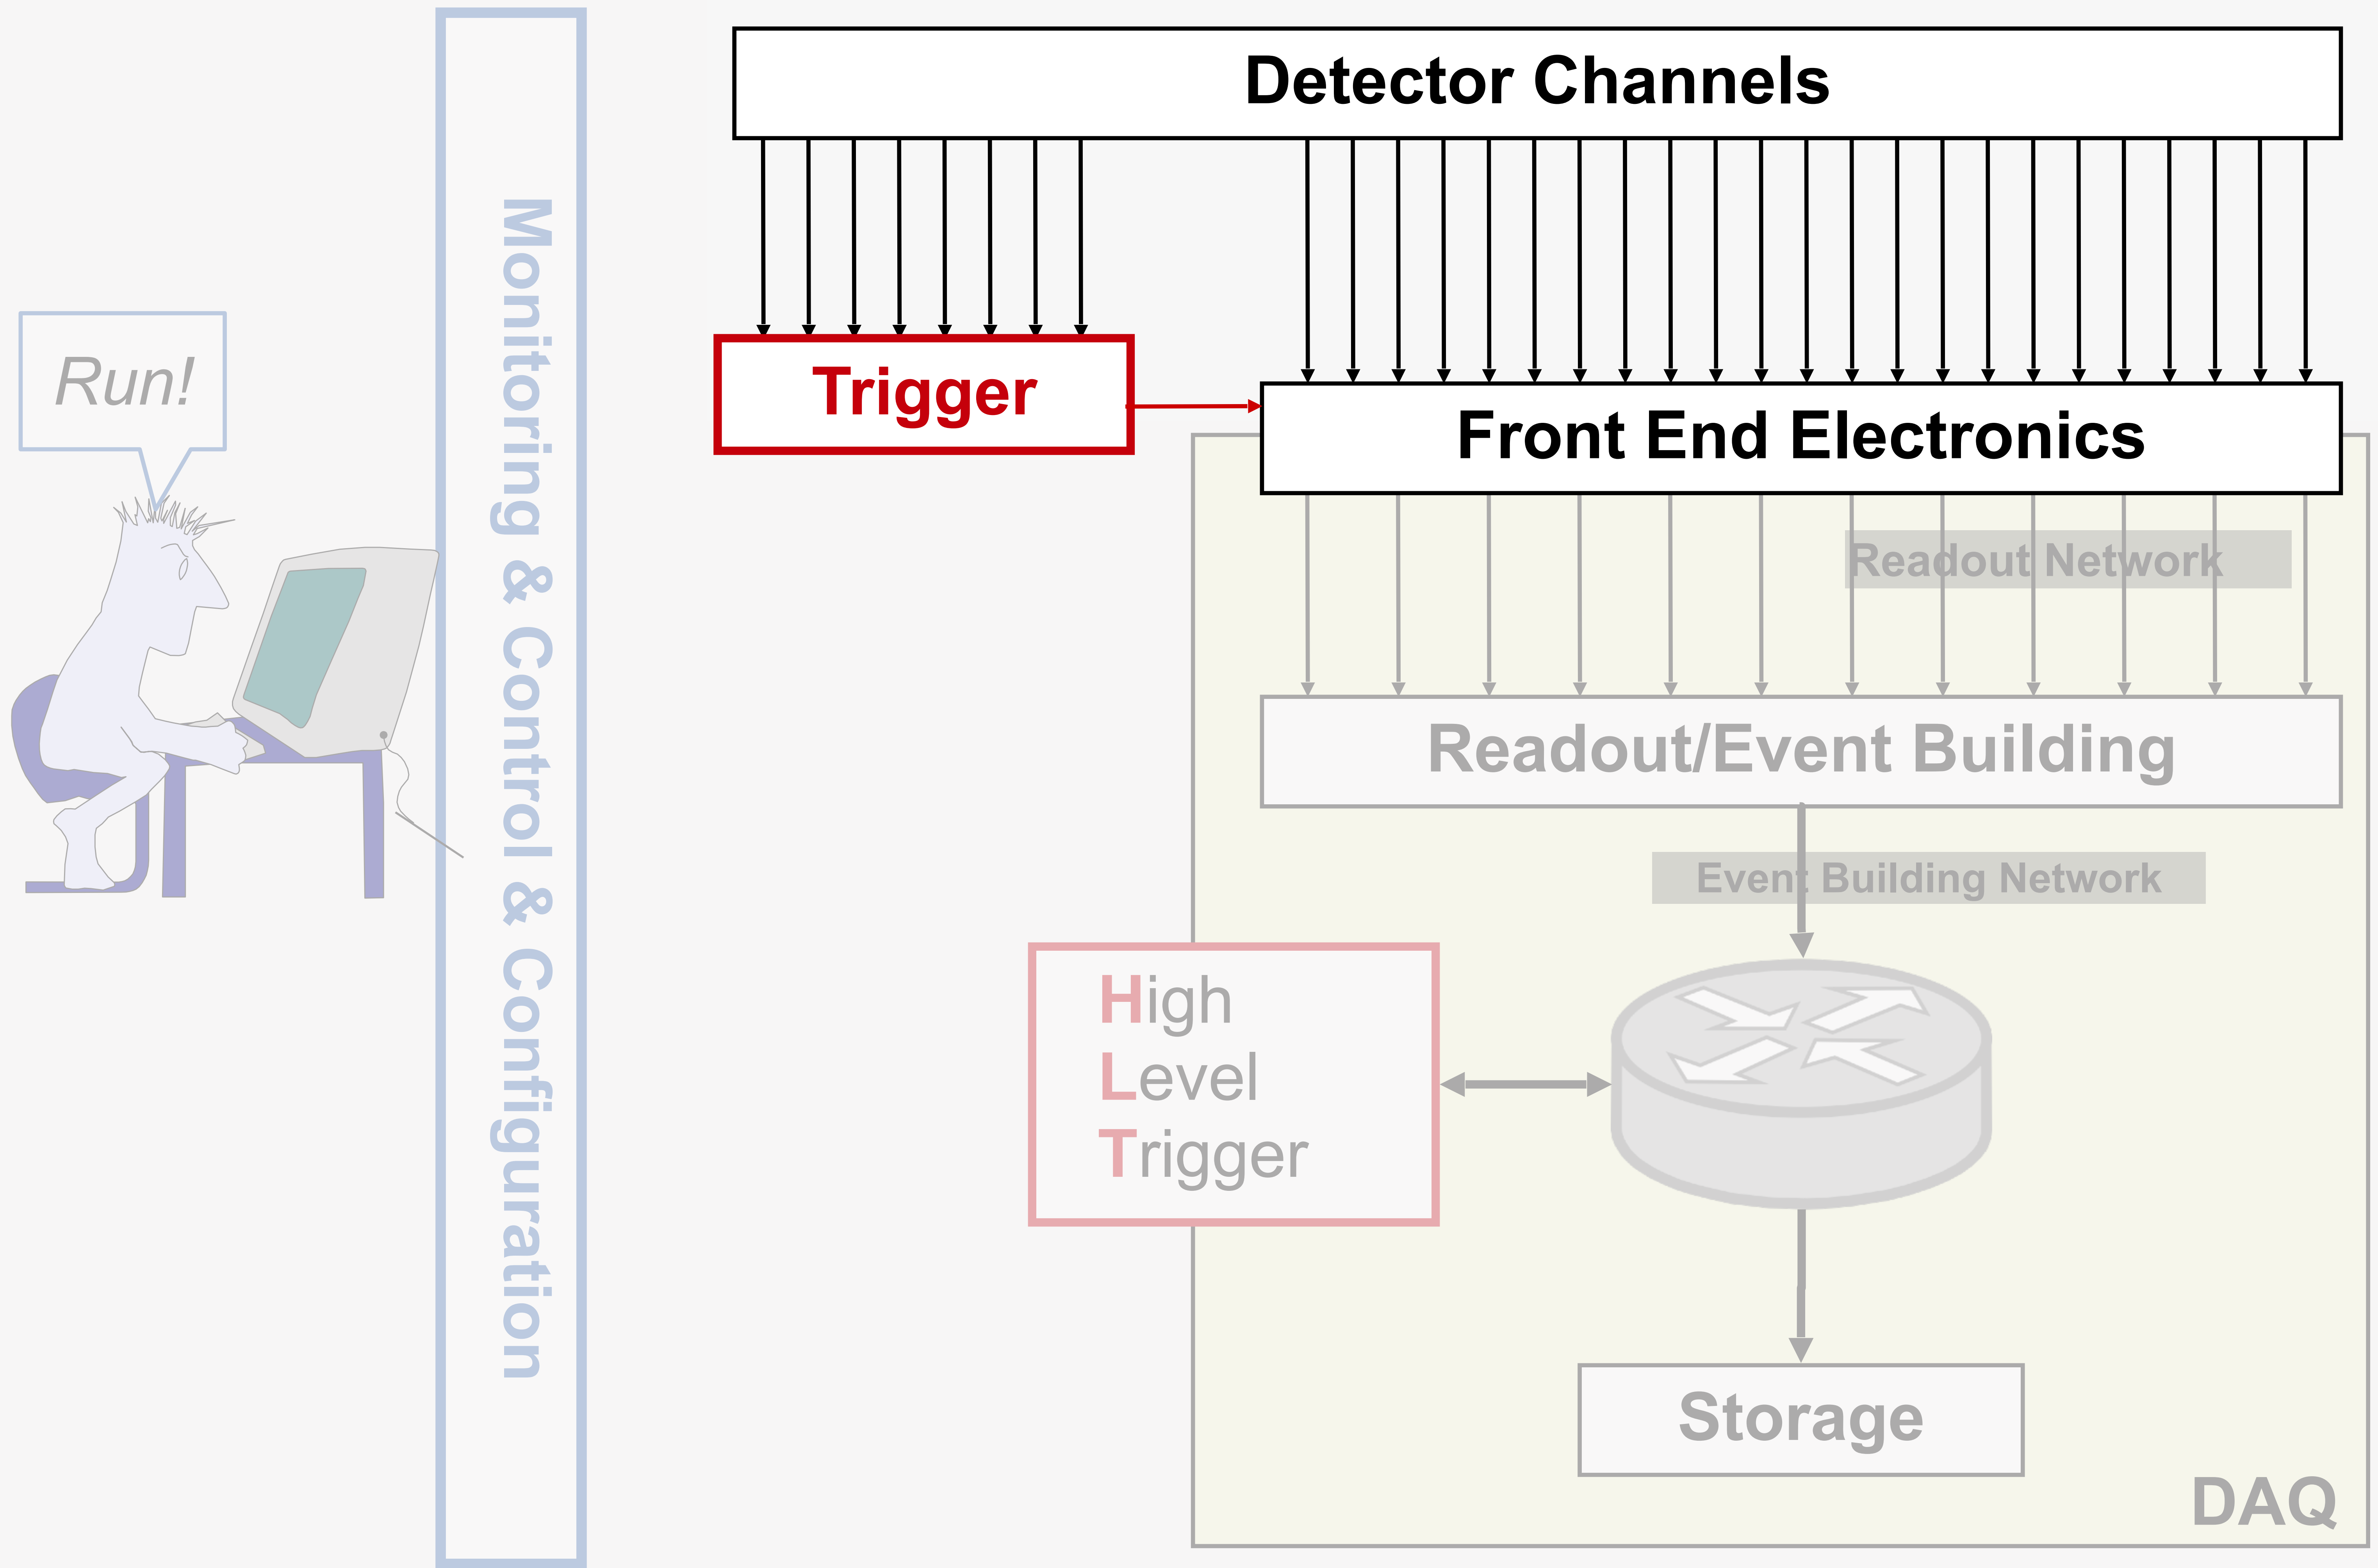
The implementation of “Trigger” has significantly evolved in the past decades

- **LEP**: trigger the sampling of (slow) detector
- **LHC**: trigger the readout of on-detector buffers (*Level-1*) or trigger logging to permanent storage (*High Level Trigger - HLT*)

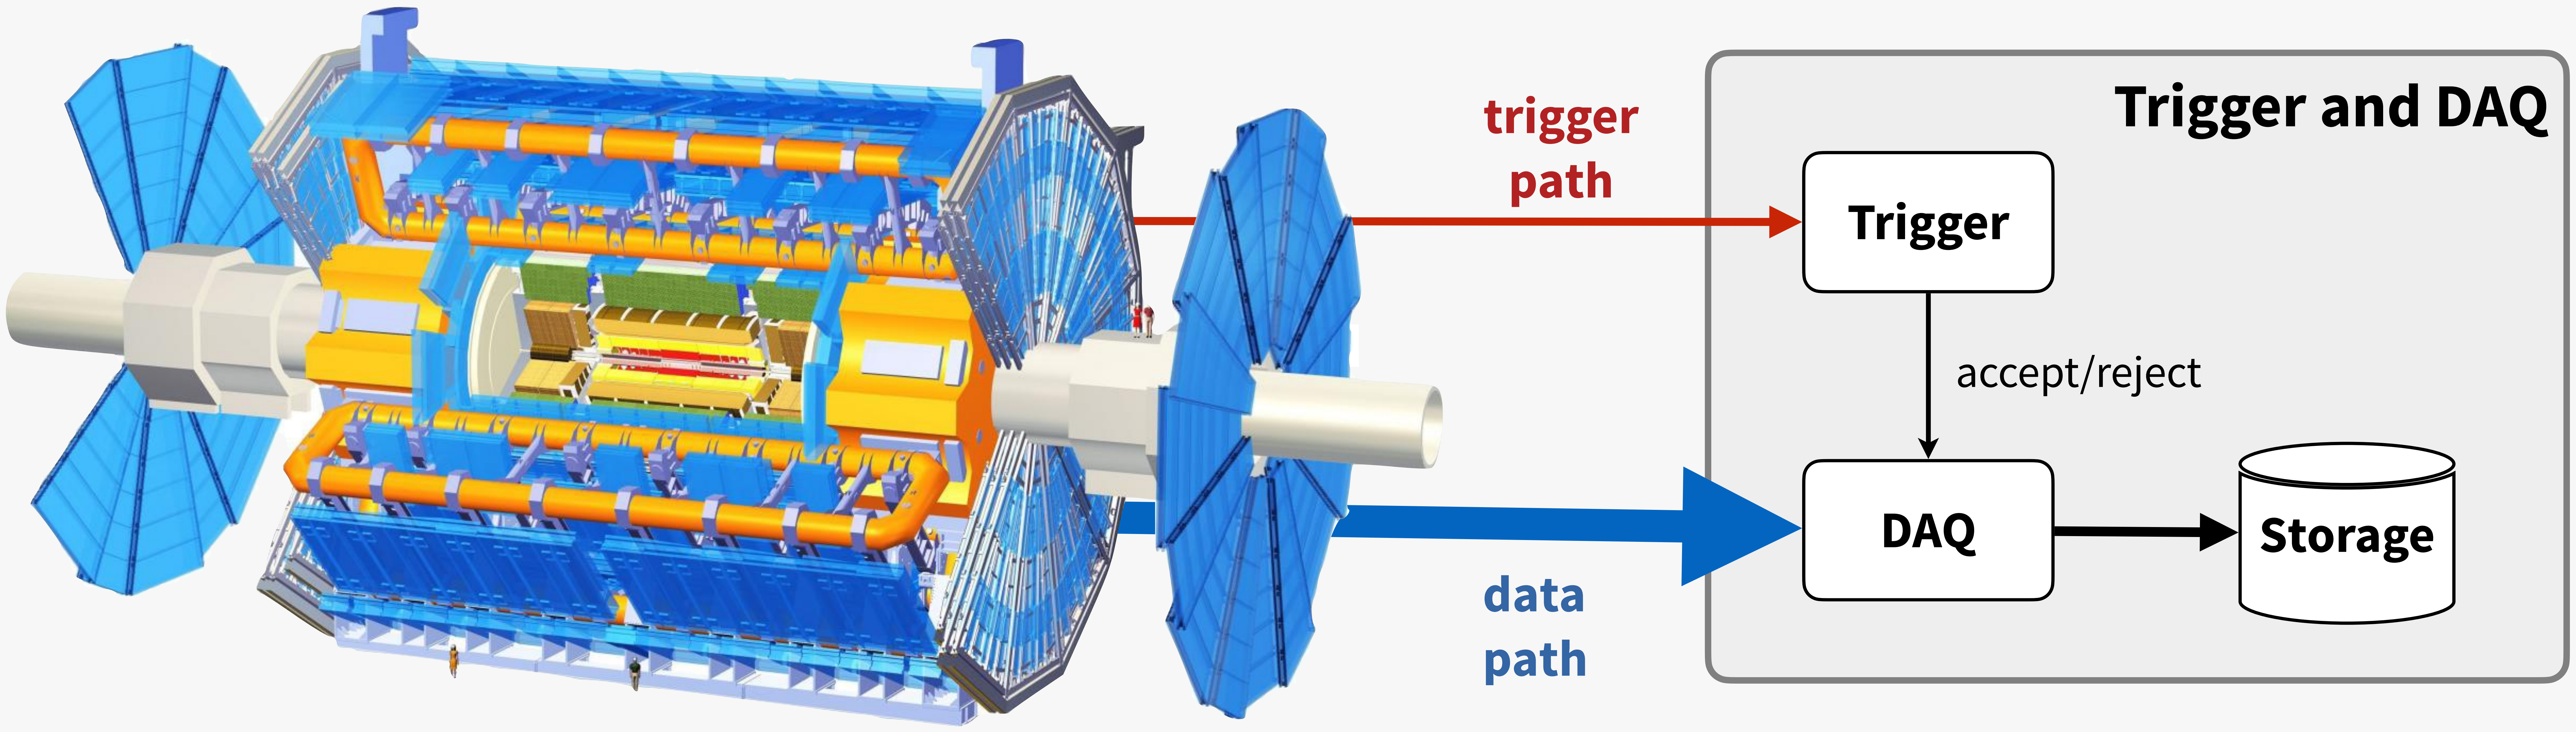
T-DAQ Architecture



T-DAQ Architecture



From detector to TDAQ



Trigger path

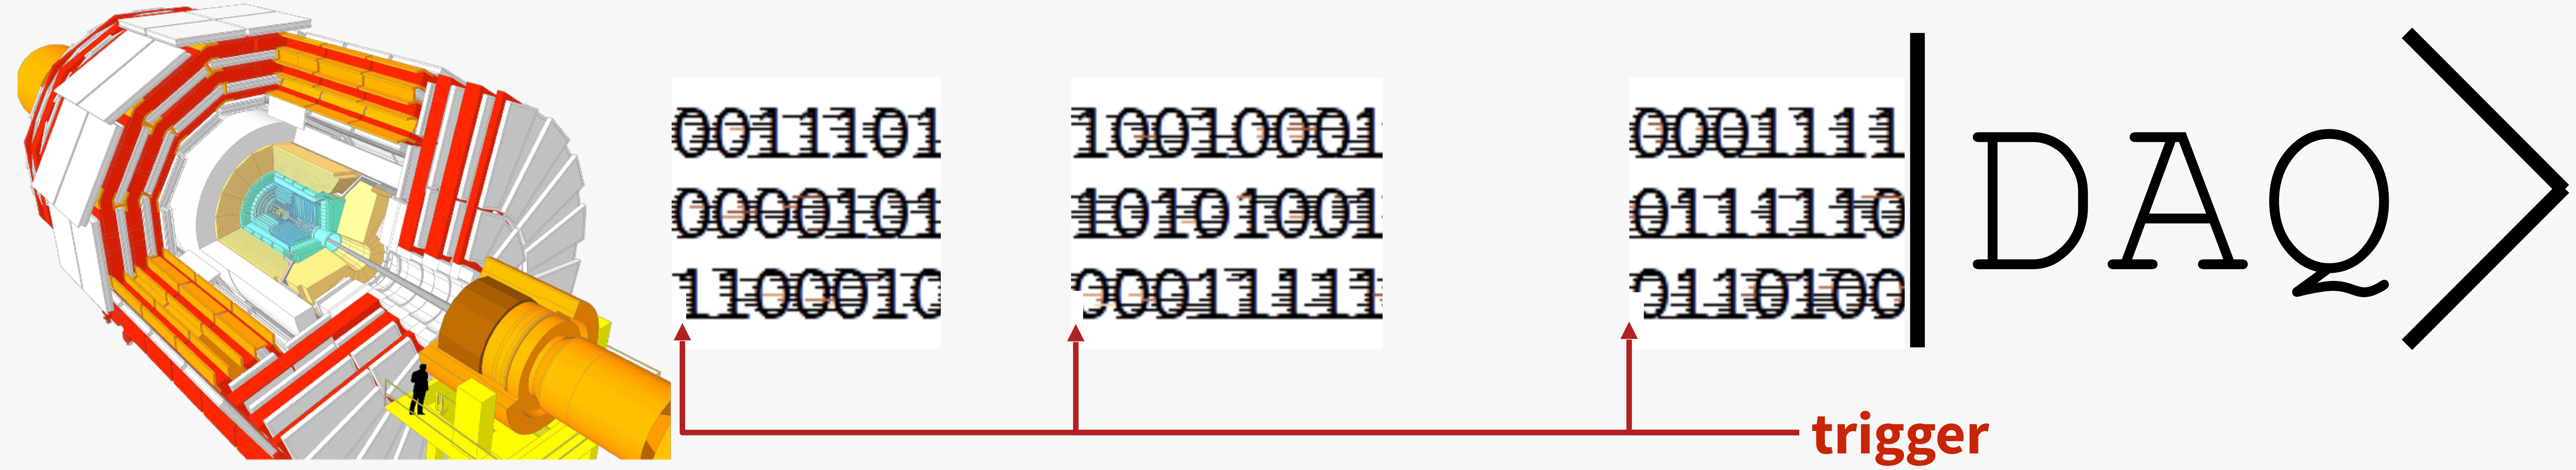
- From specific detectors to trigger logic
- Continuous streaming of trigger data
- Dedicated connections

Data path

- From all the detectors to readout
- Transmission on positive trigger decision

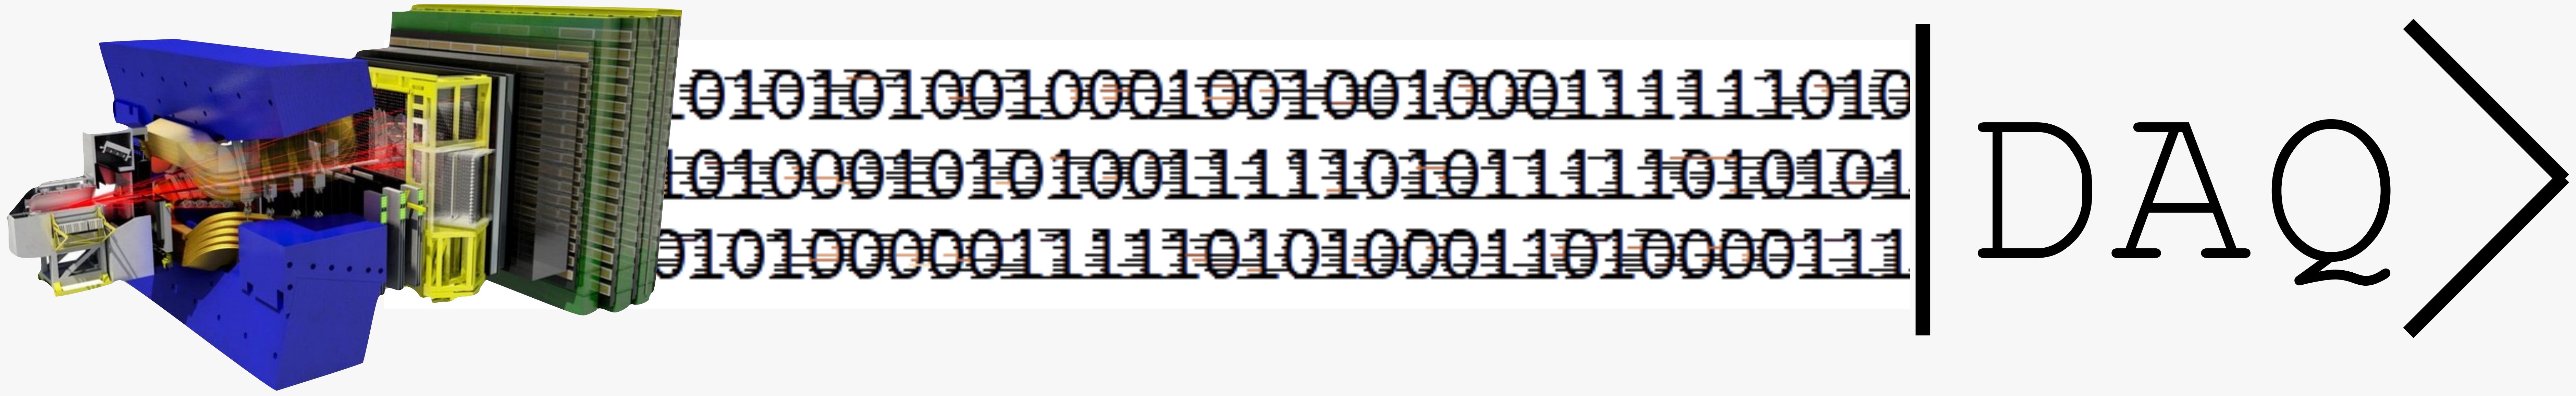
Readout: Triggered vs Streaming

Triggered: data is readout from detector only when a trigger signal is raised

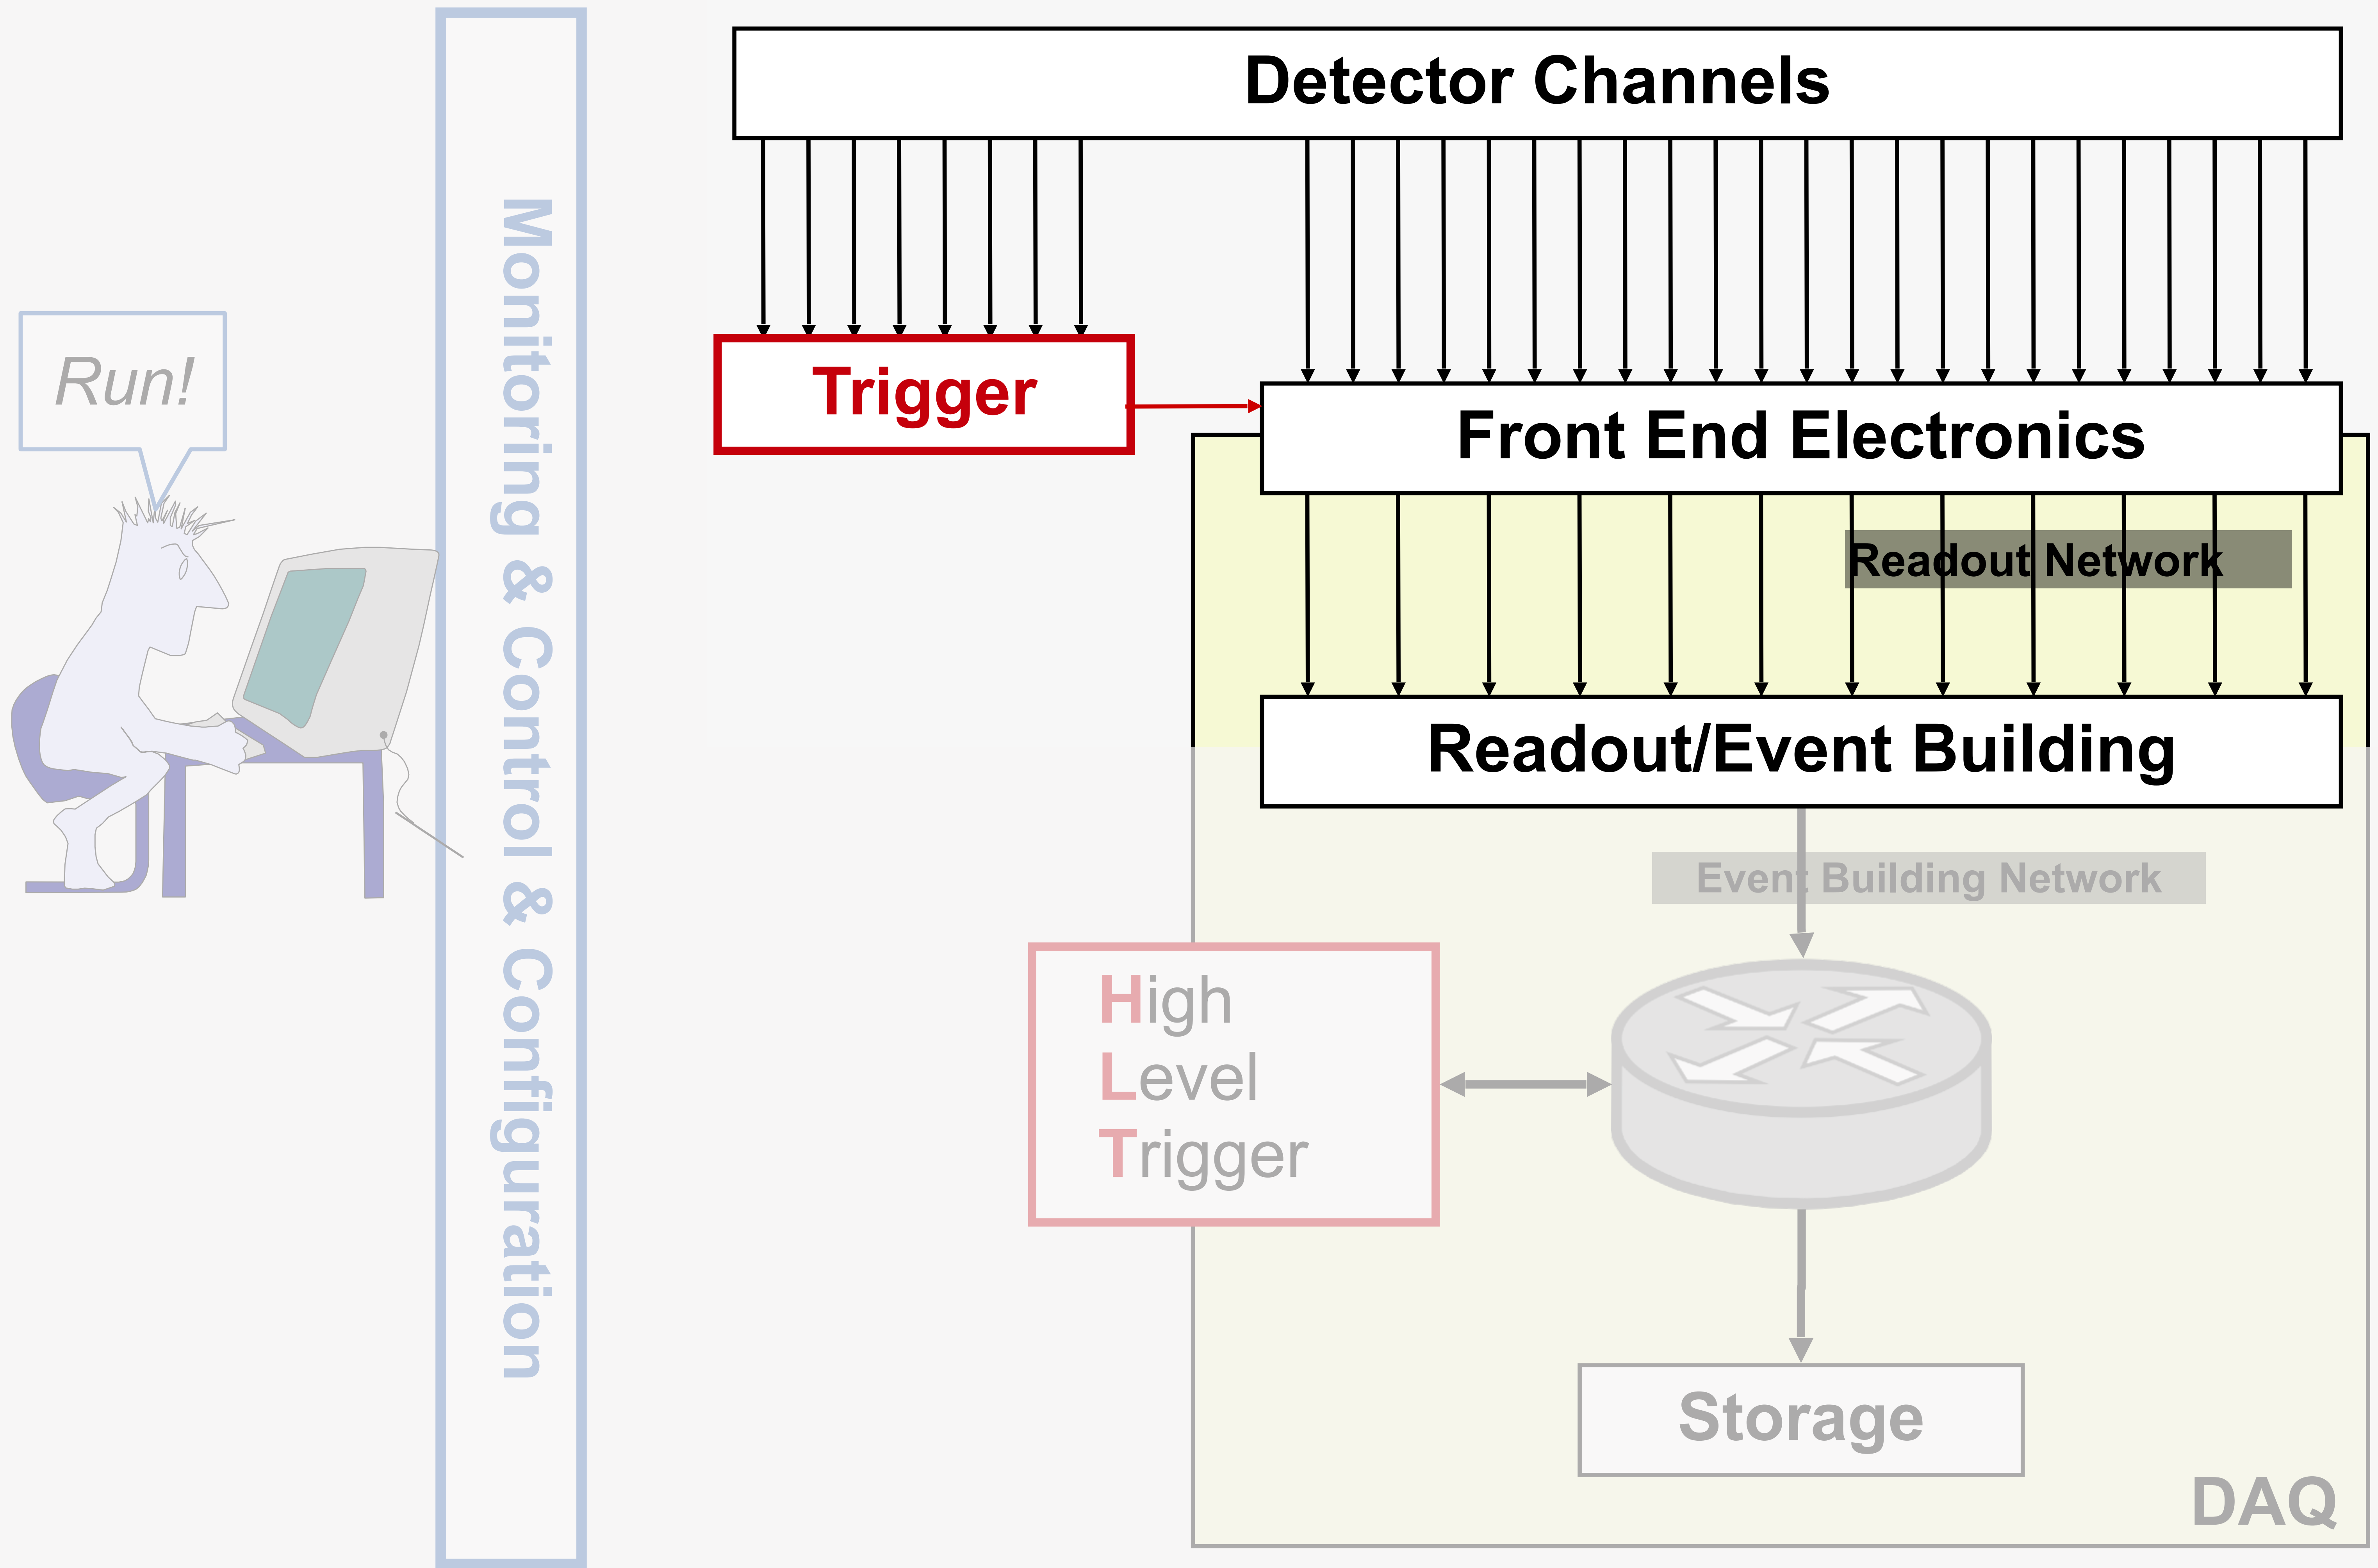


Streaming: detector pushes all its data and the downstream DAQ must keep the pace

- data reduction still takes place, but post readout



T-DAQ Architecture



Field Programmable Gate Arrays

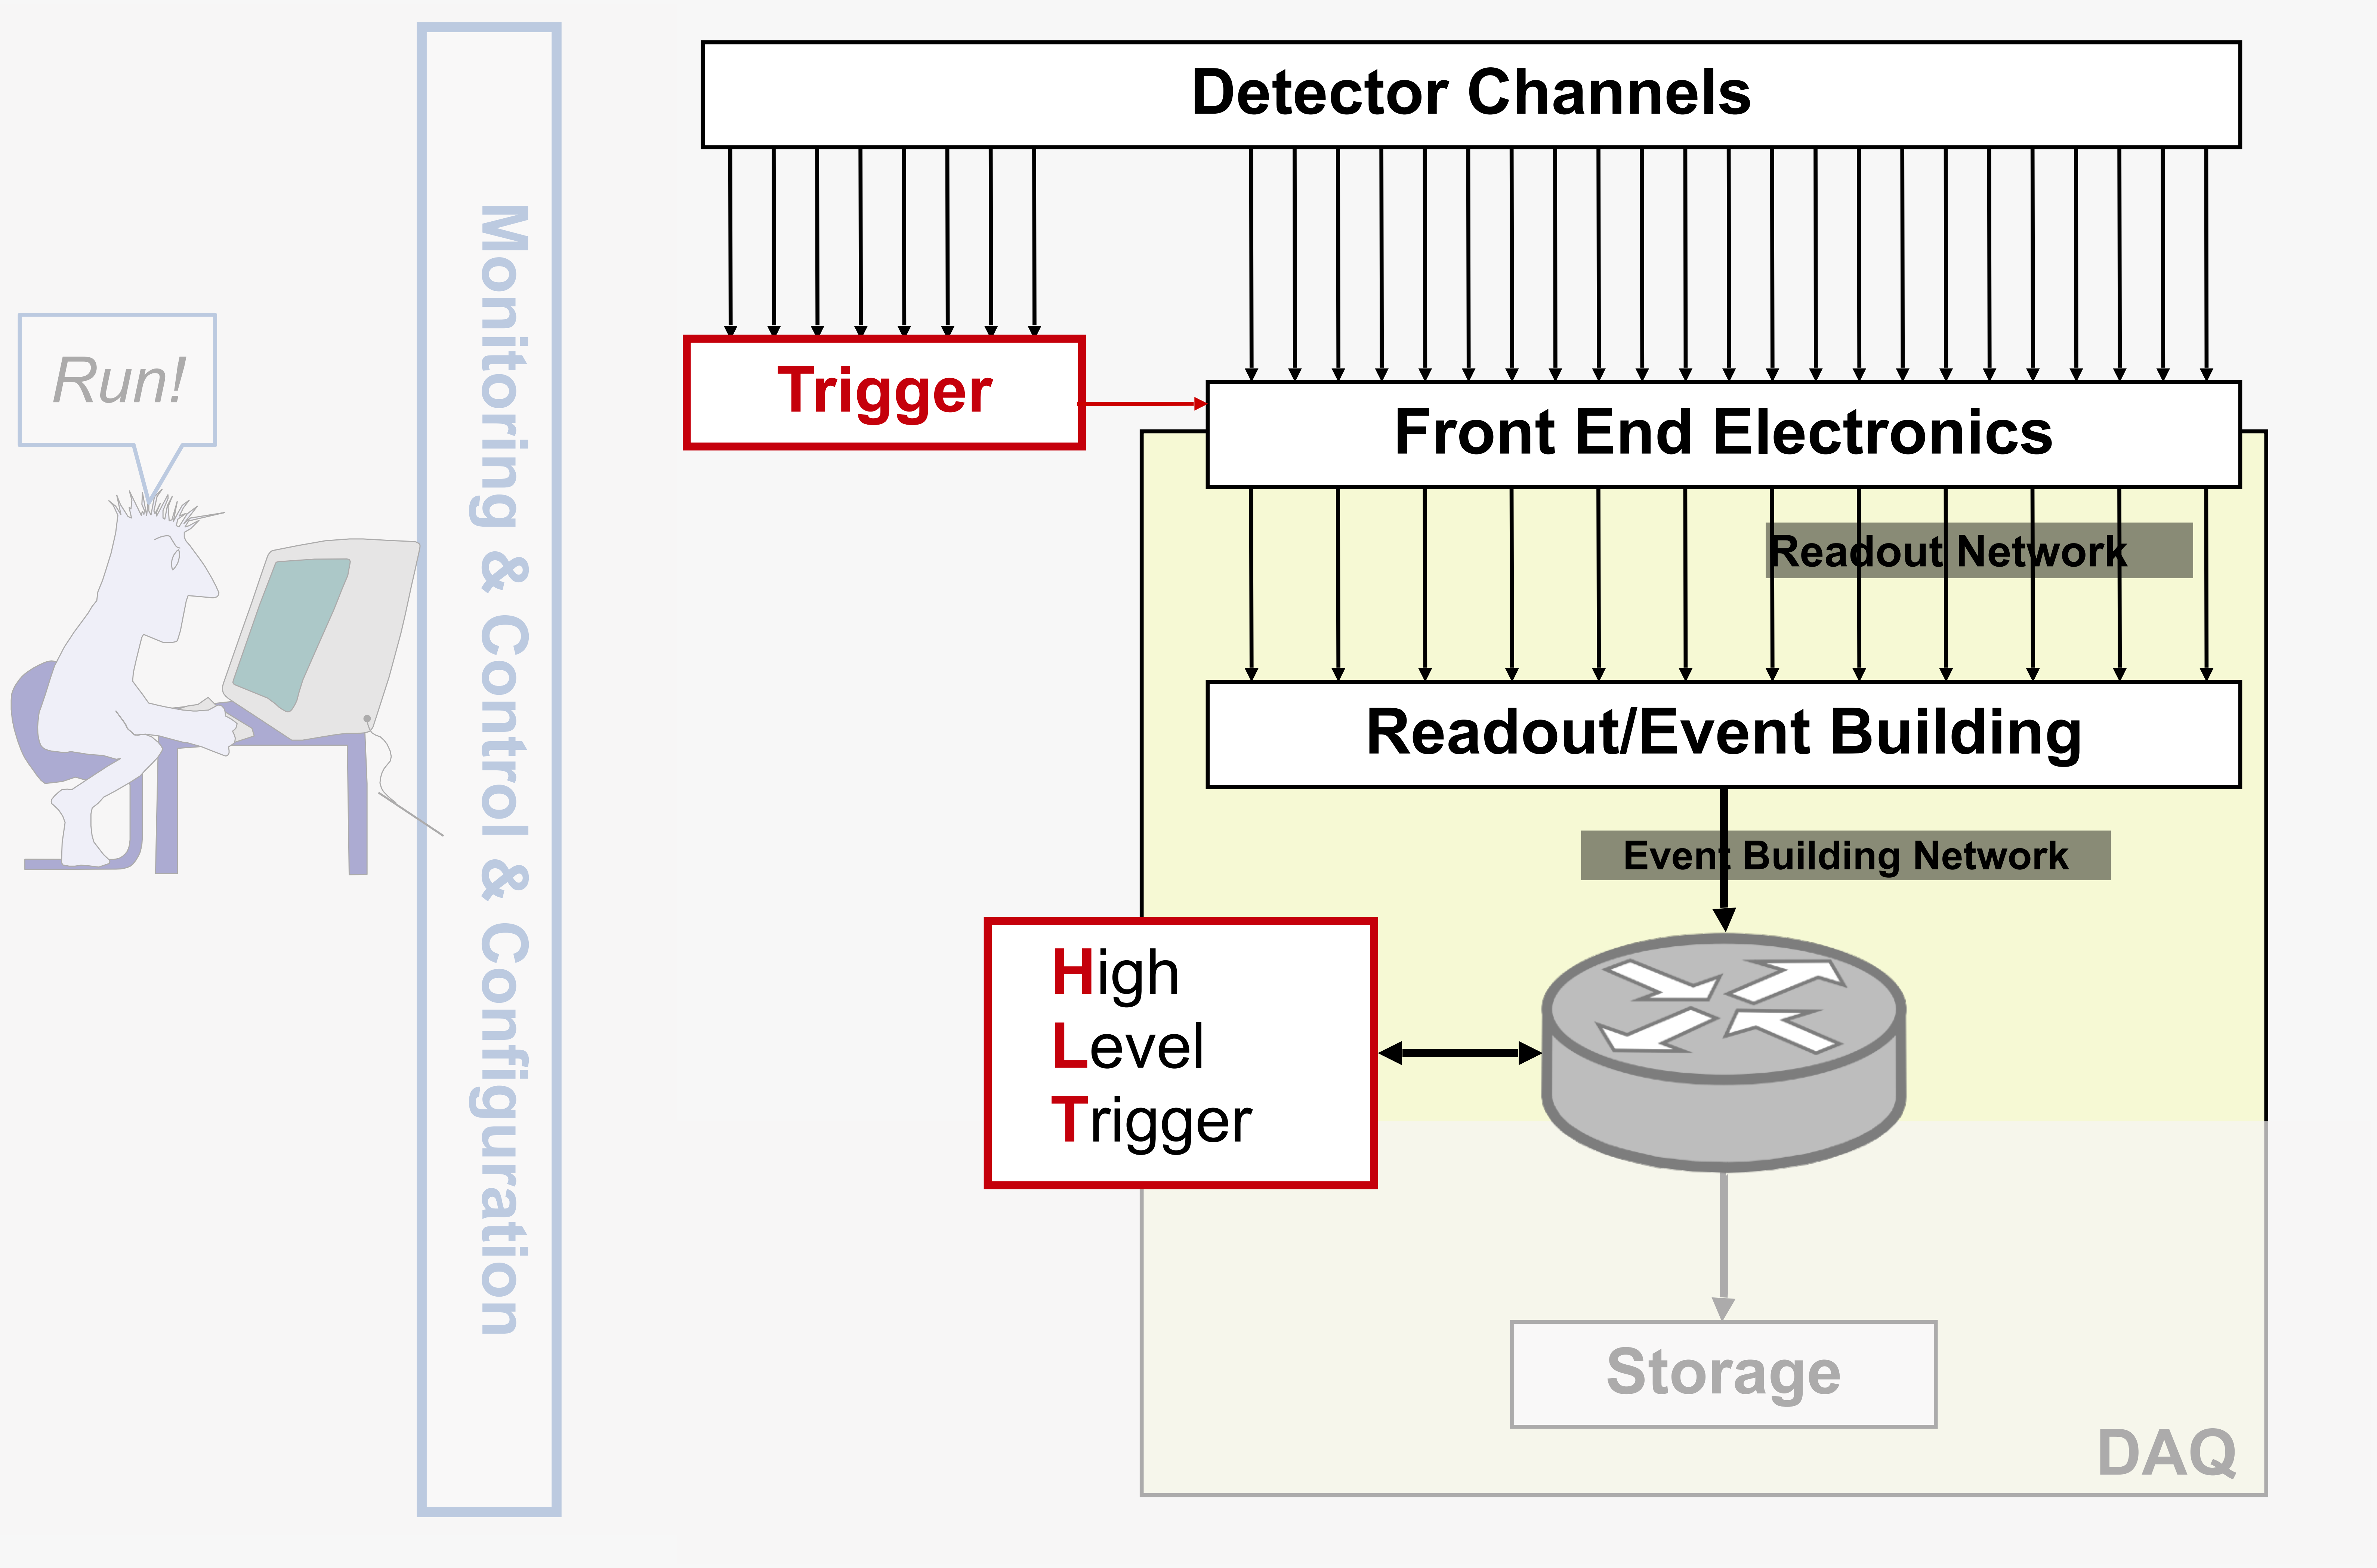
FPGAs are becoming TDAQ's bread & butter

- Signal processing, data formatting, natively parallel tasks (e.g. pattern recognition), machine learning, …

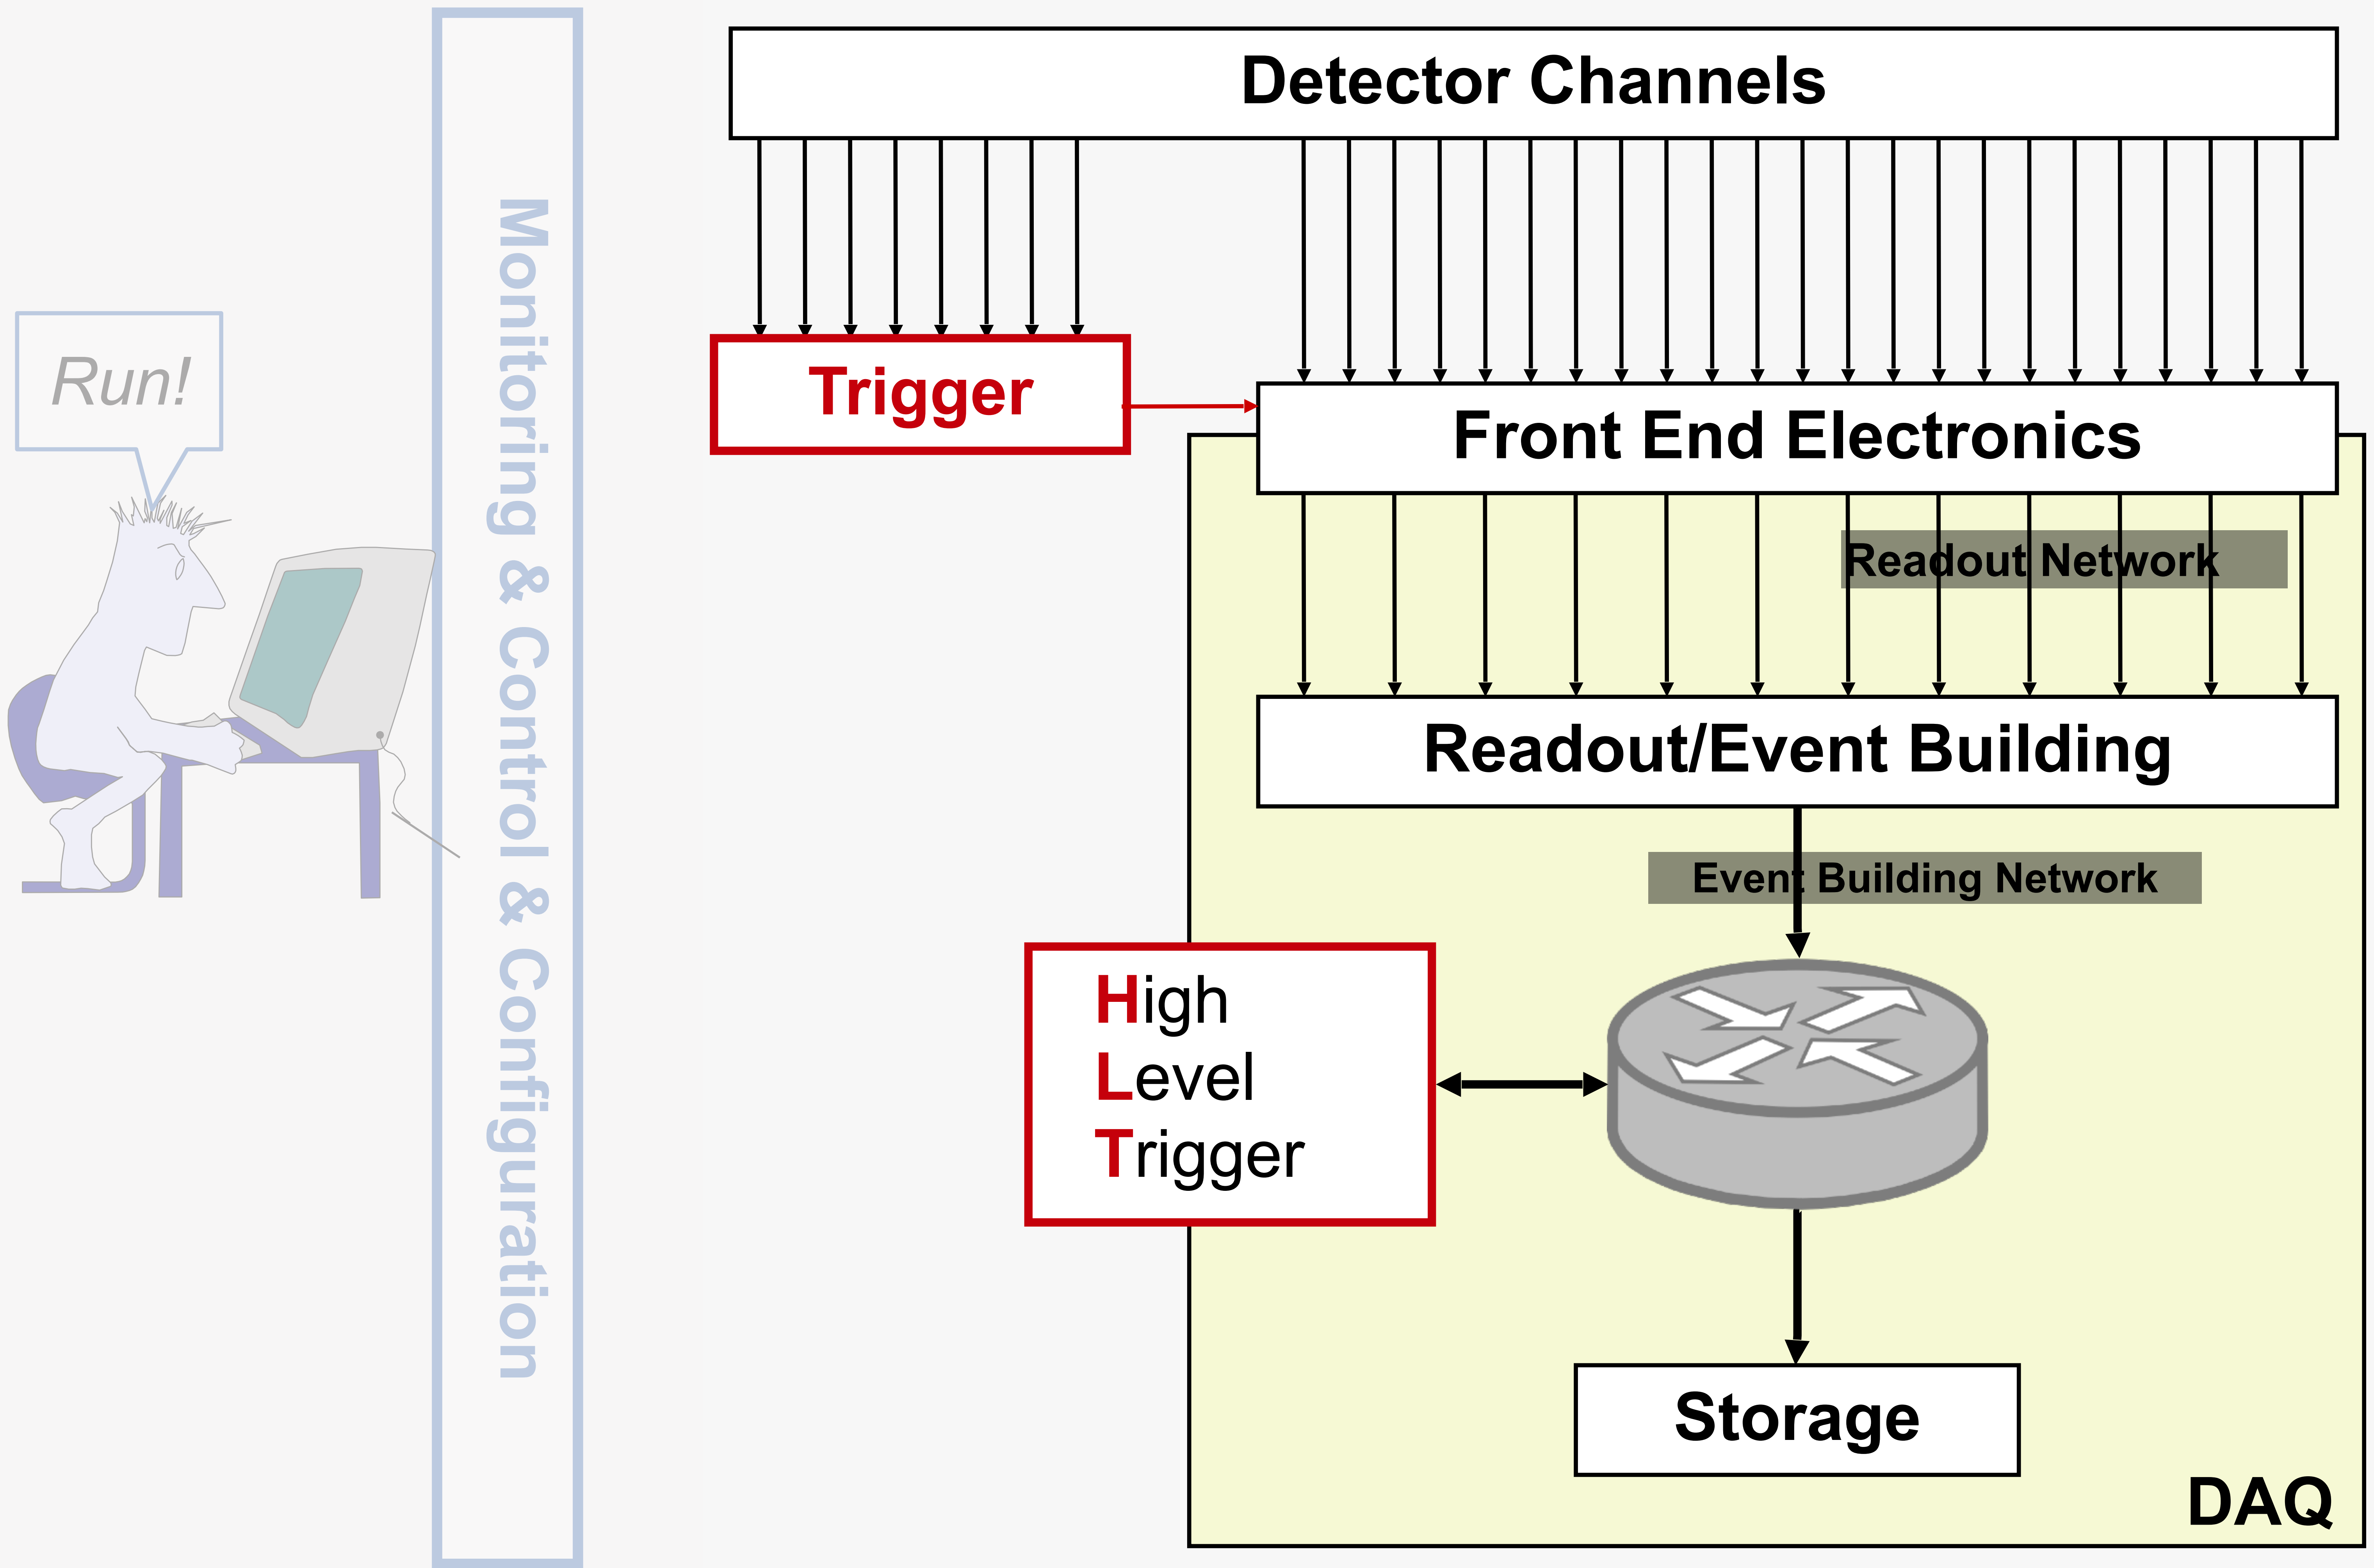
FPGA Programming Lecture - Dr. Kristian Harder

- Plenty of gory details about LUTs, BRAMs and VHDL to keep you awake at night!

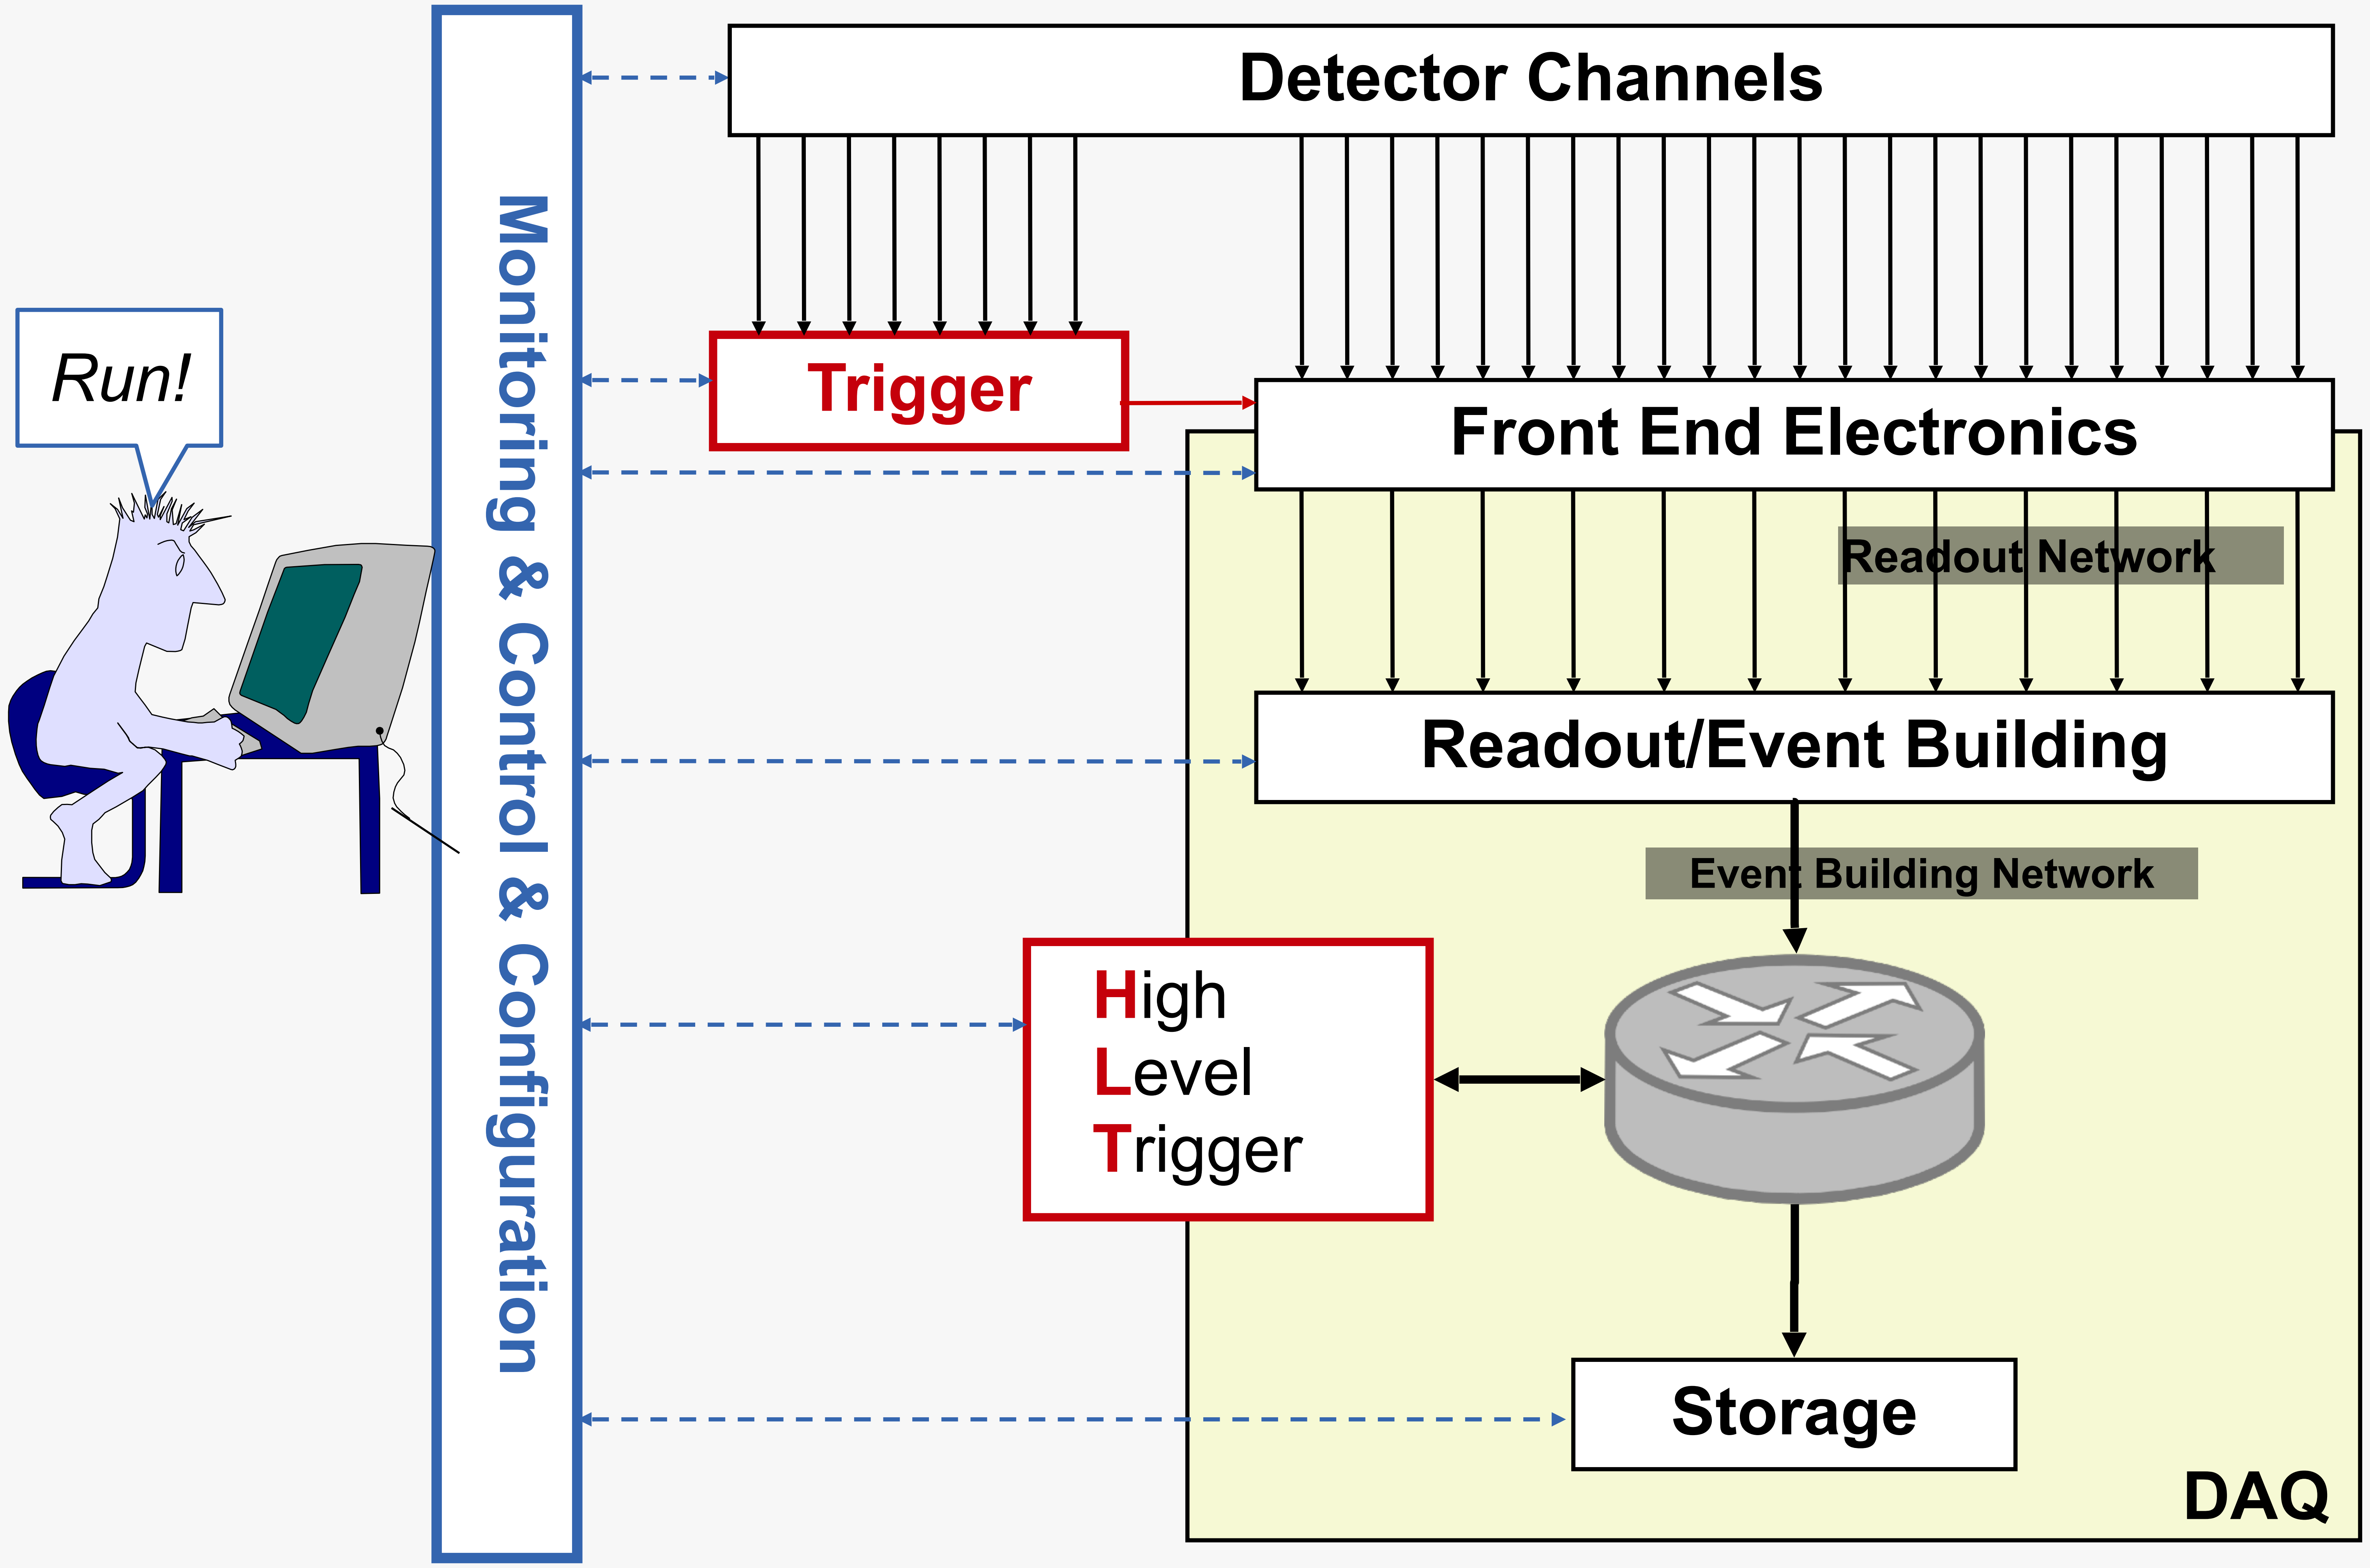
T-DAQ Architecture



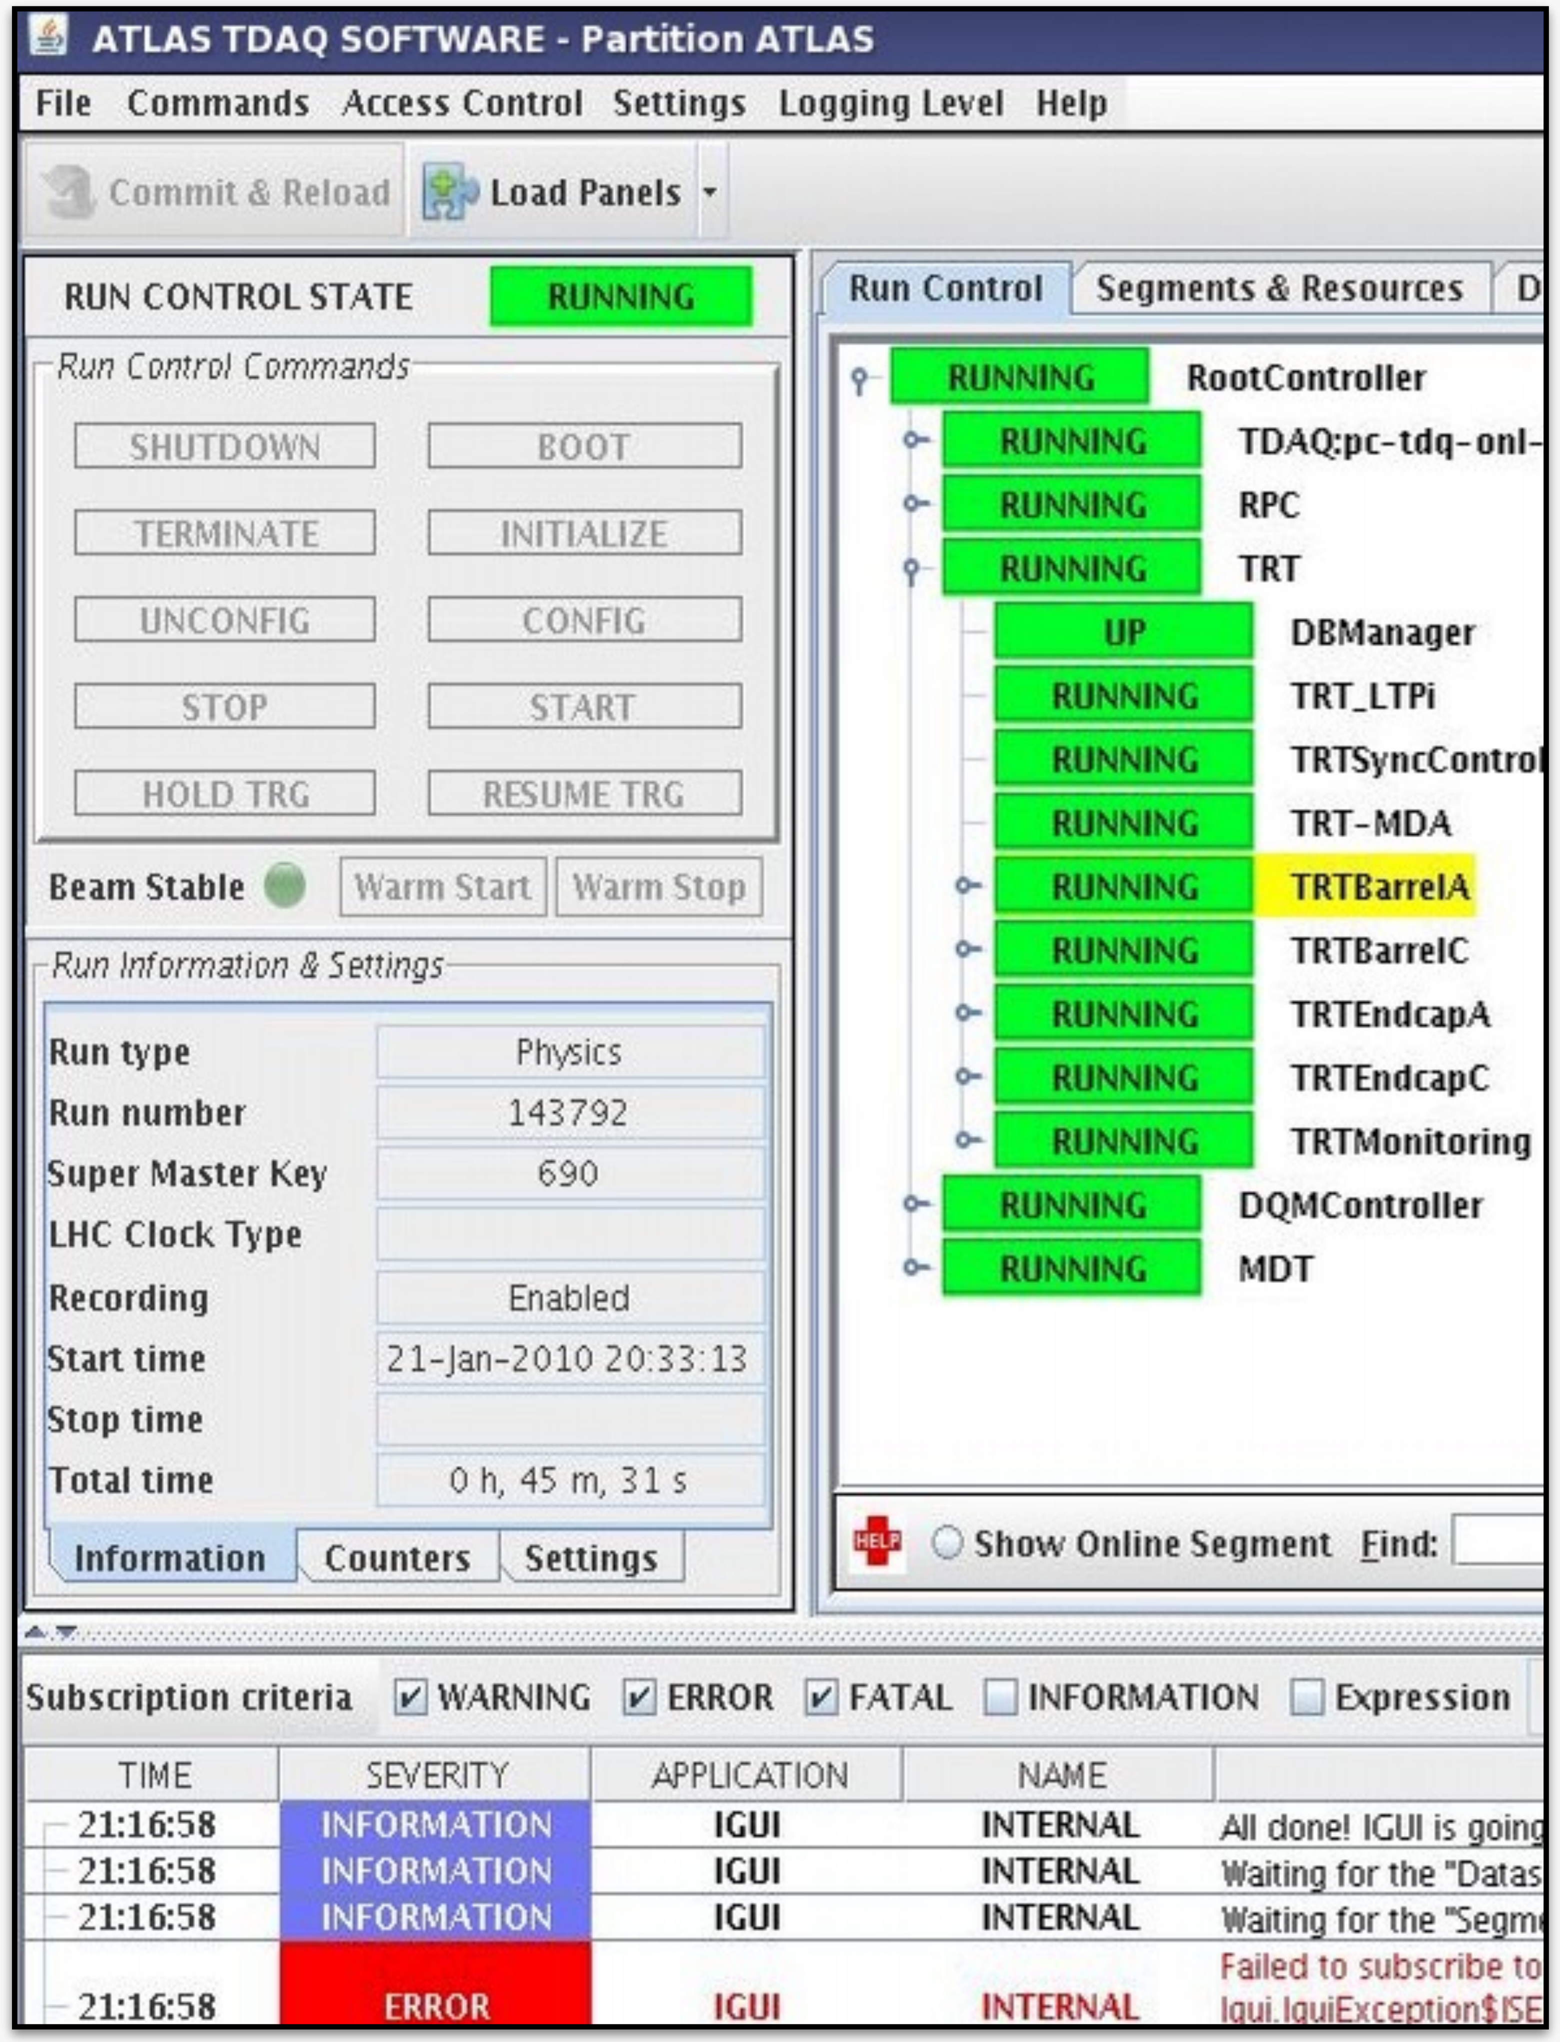
T-DAQ Architecture



T-DAQ Architecture



The glue of your experiment



Configuration

- Ensemble of detectors, trigger and DAQ parameters defining the system behaviour during data taking

Control

- Orchestrate applications participating to data taking
- Via distributed Finite State Machine

Monitoring

- Of data taking operations
  - What is going on?
  - What happened?
  - When?
  - Where?

Outline

1. Introduction

1.1. What is DAQ?

4. DAQ Challenges at the LHC

with a toy model

Basic DAQ: periodic trigger

Eg: measure temperature at a fixed frequency

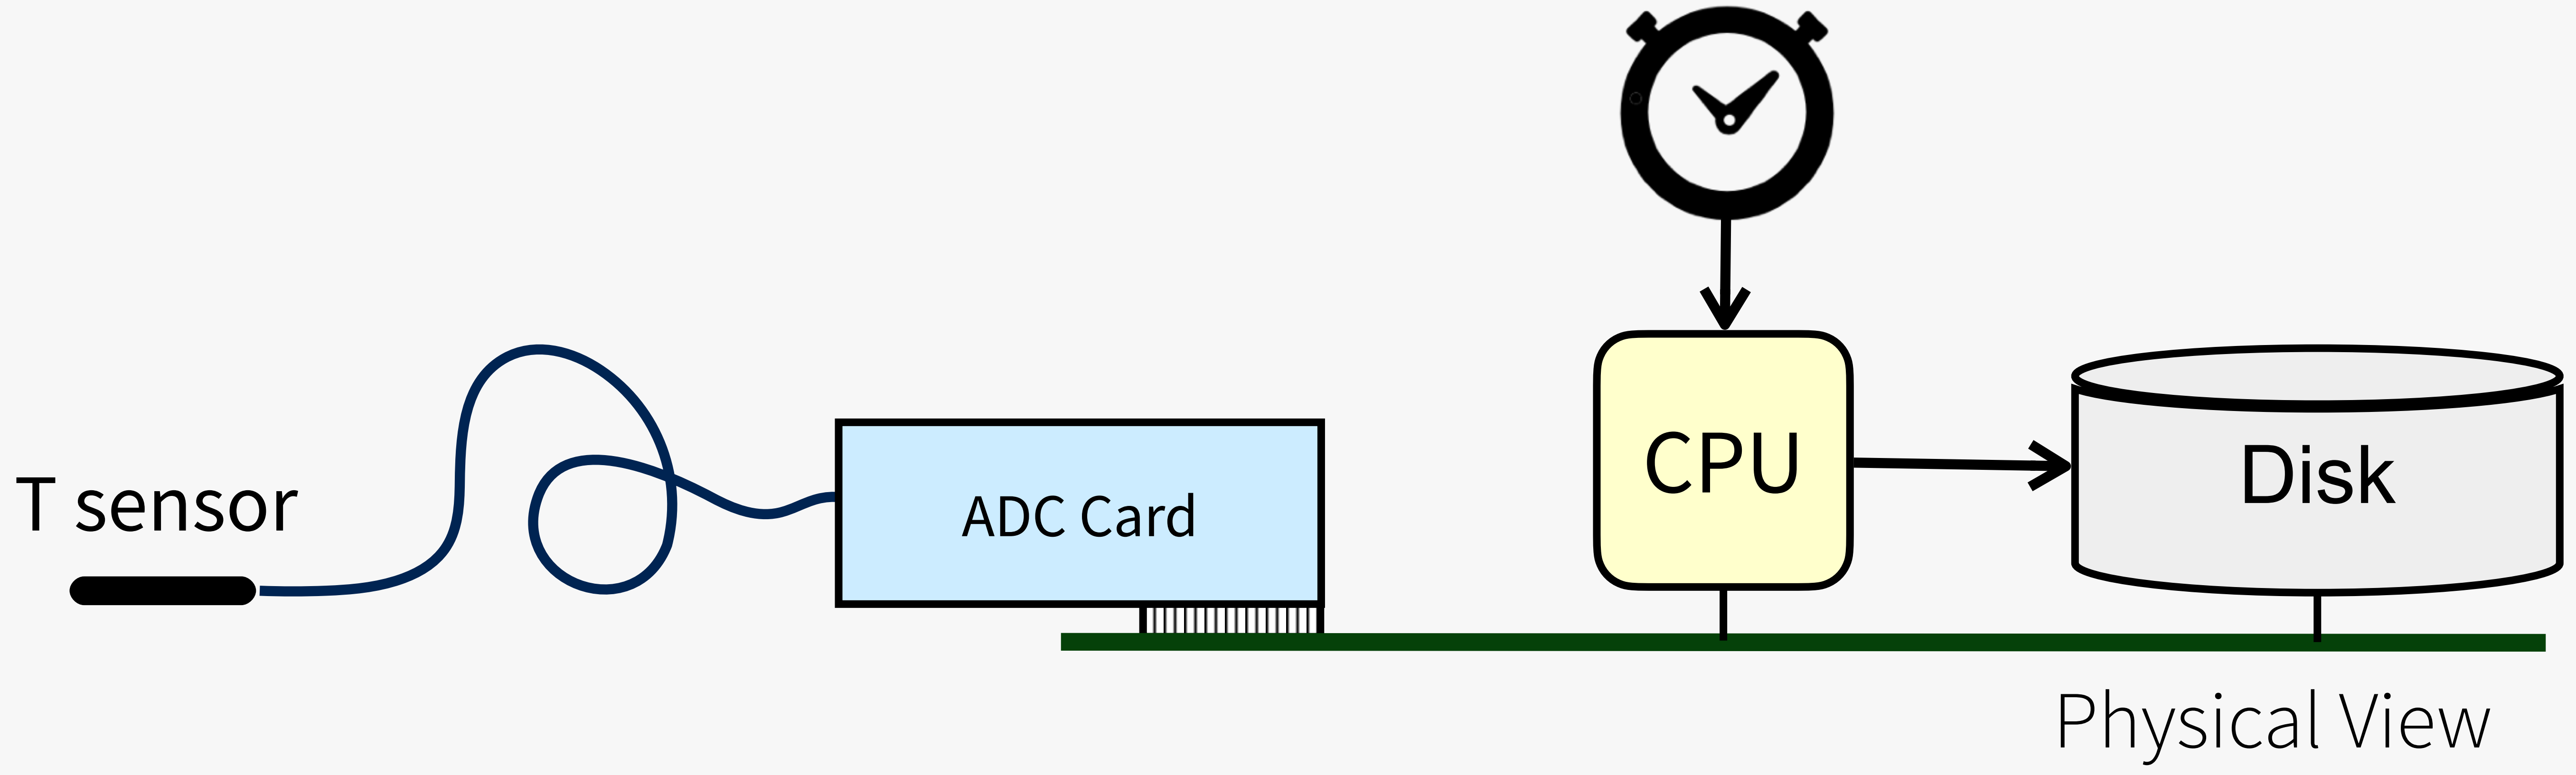
- Clock triggered

ADC performs analog to digital conversion, digitization (our front-end electronics)

- Encoding analog value into binary representation

CPU does

- Readout, Processing, Storage



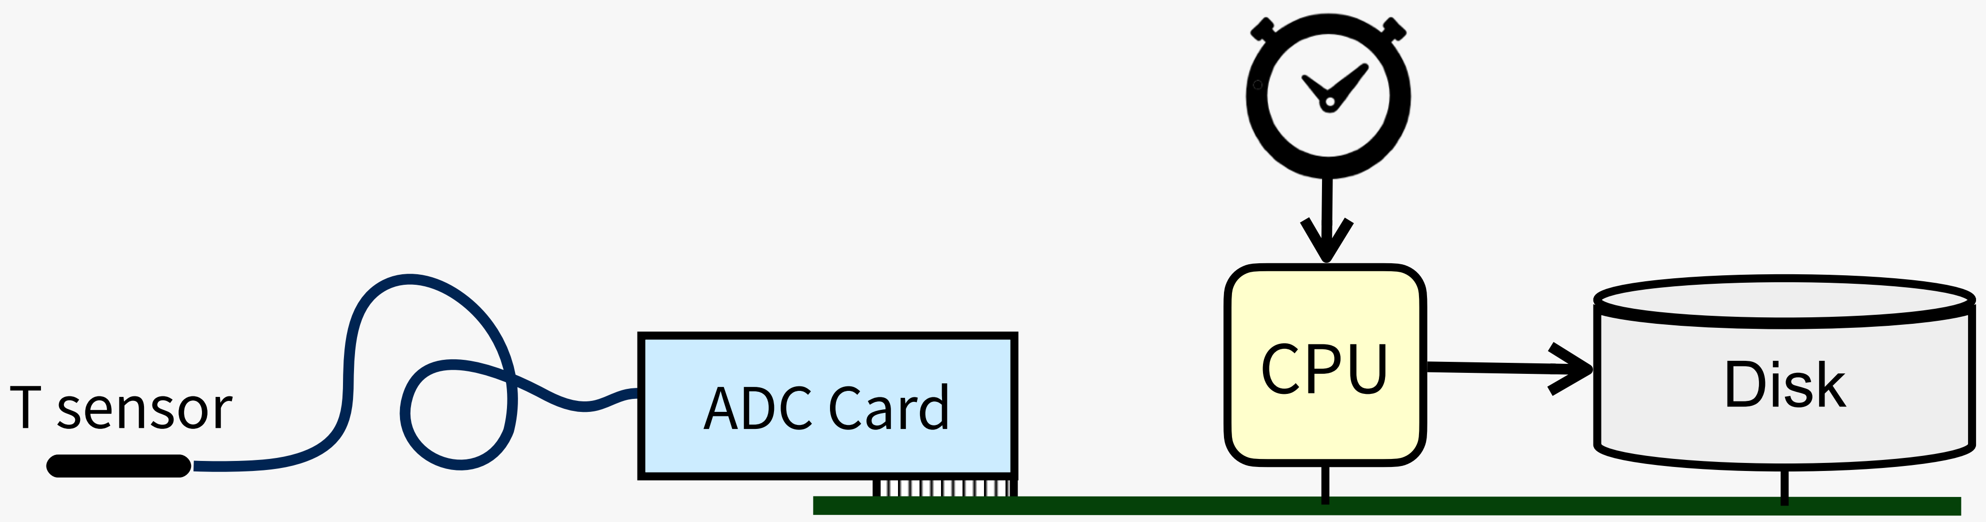
Basic DAQ: periodic trigger

System clearly limited by the time τ to process an “event”

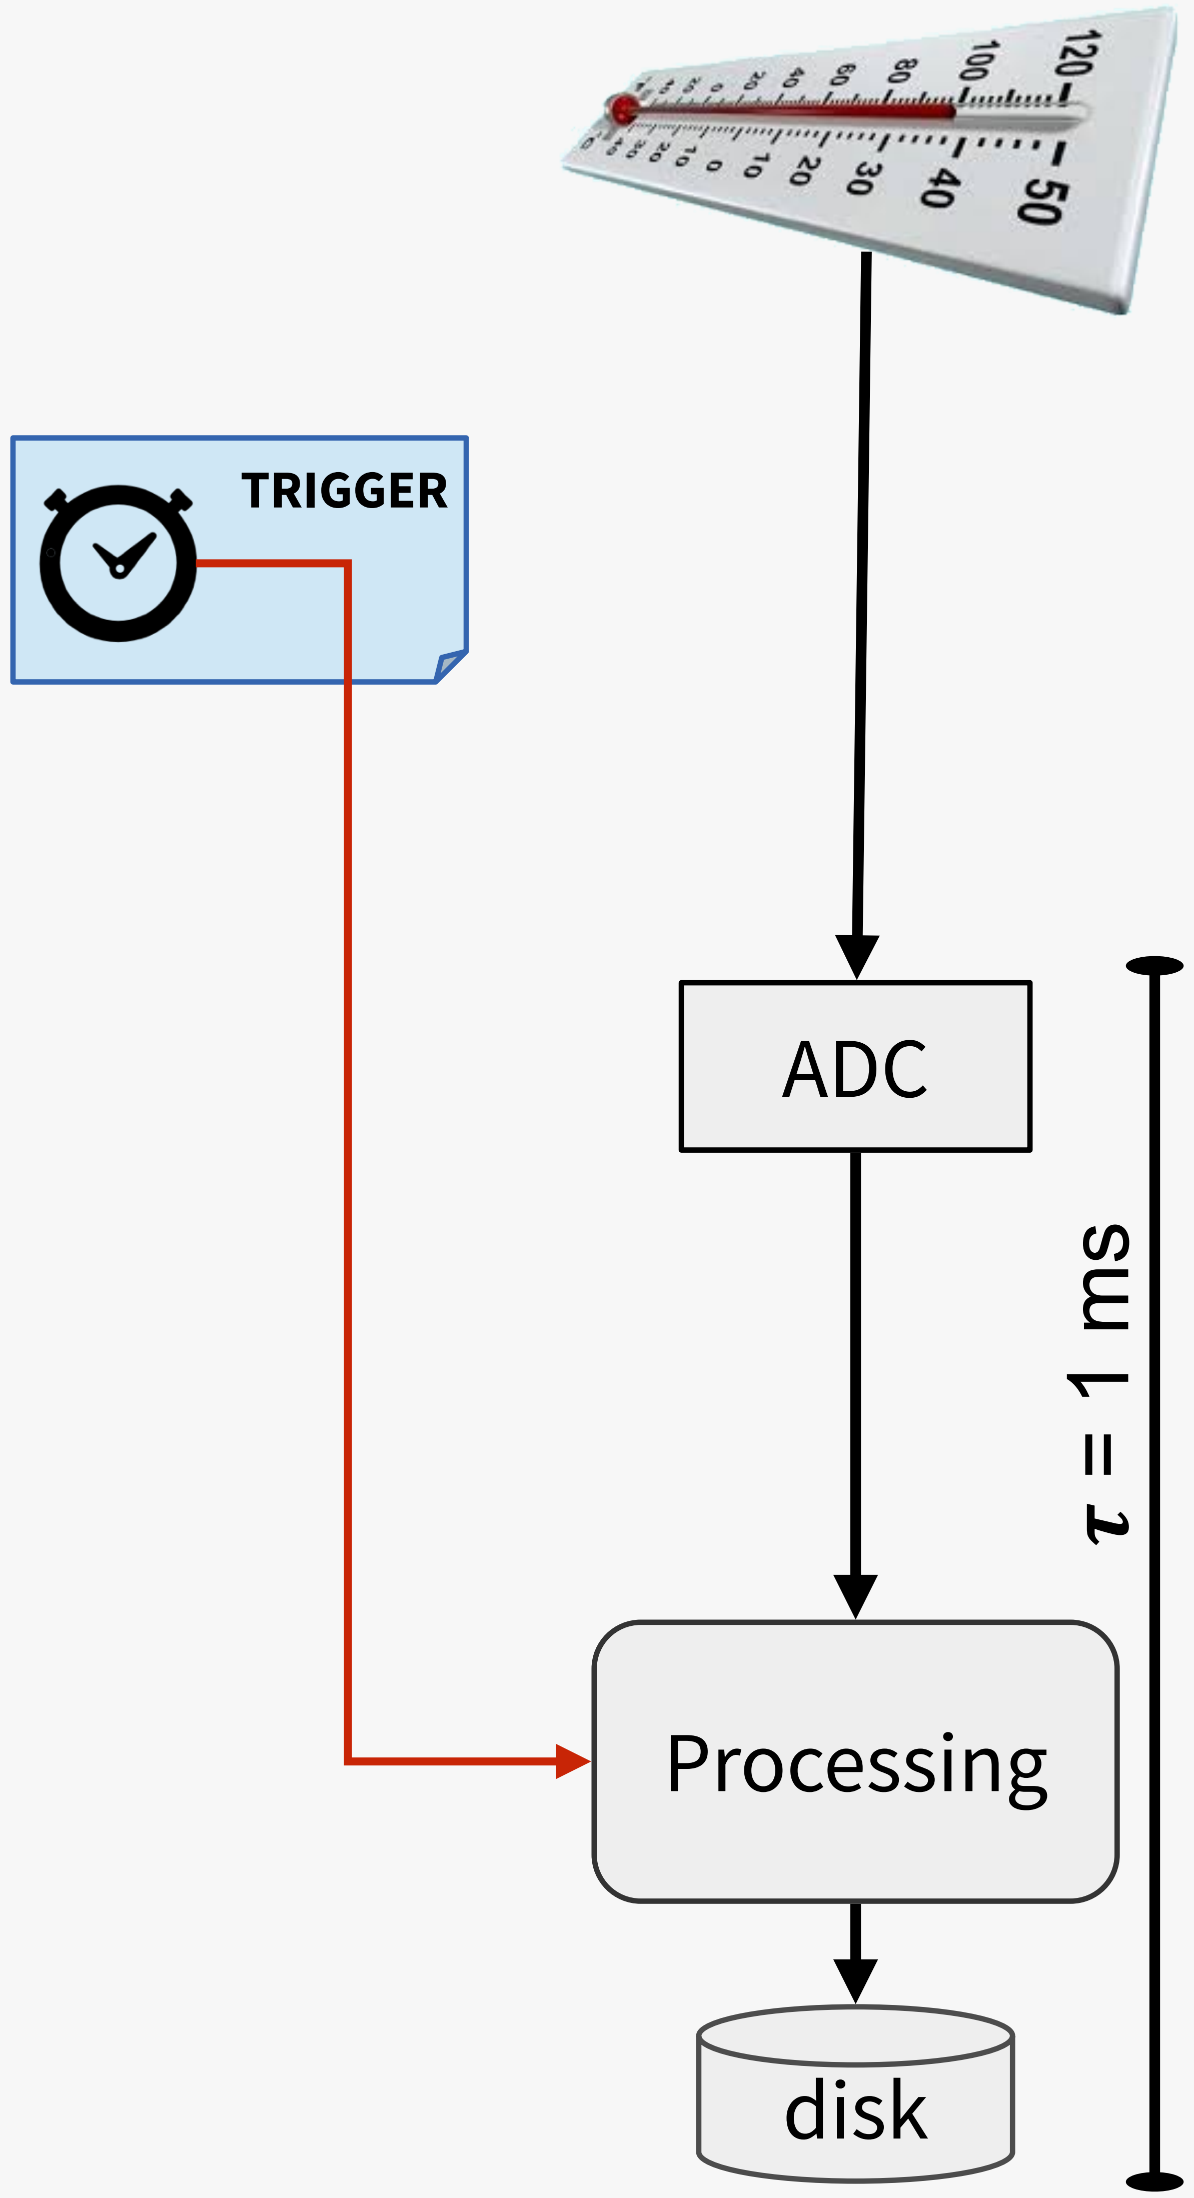
- ADC conversion +
  CPU processing +
  Storage

The DAQ maximum sustainable rate is simply the inverse of τ, e.g.:

- E.g.: $\tau = 1$ ms $R = 1/\tau = 1$ kHz



Physical View



Basic DAQ: "real" trigger

Events asynchronous and unpredictable

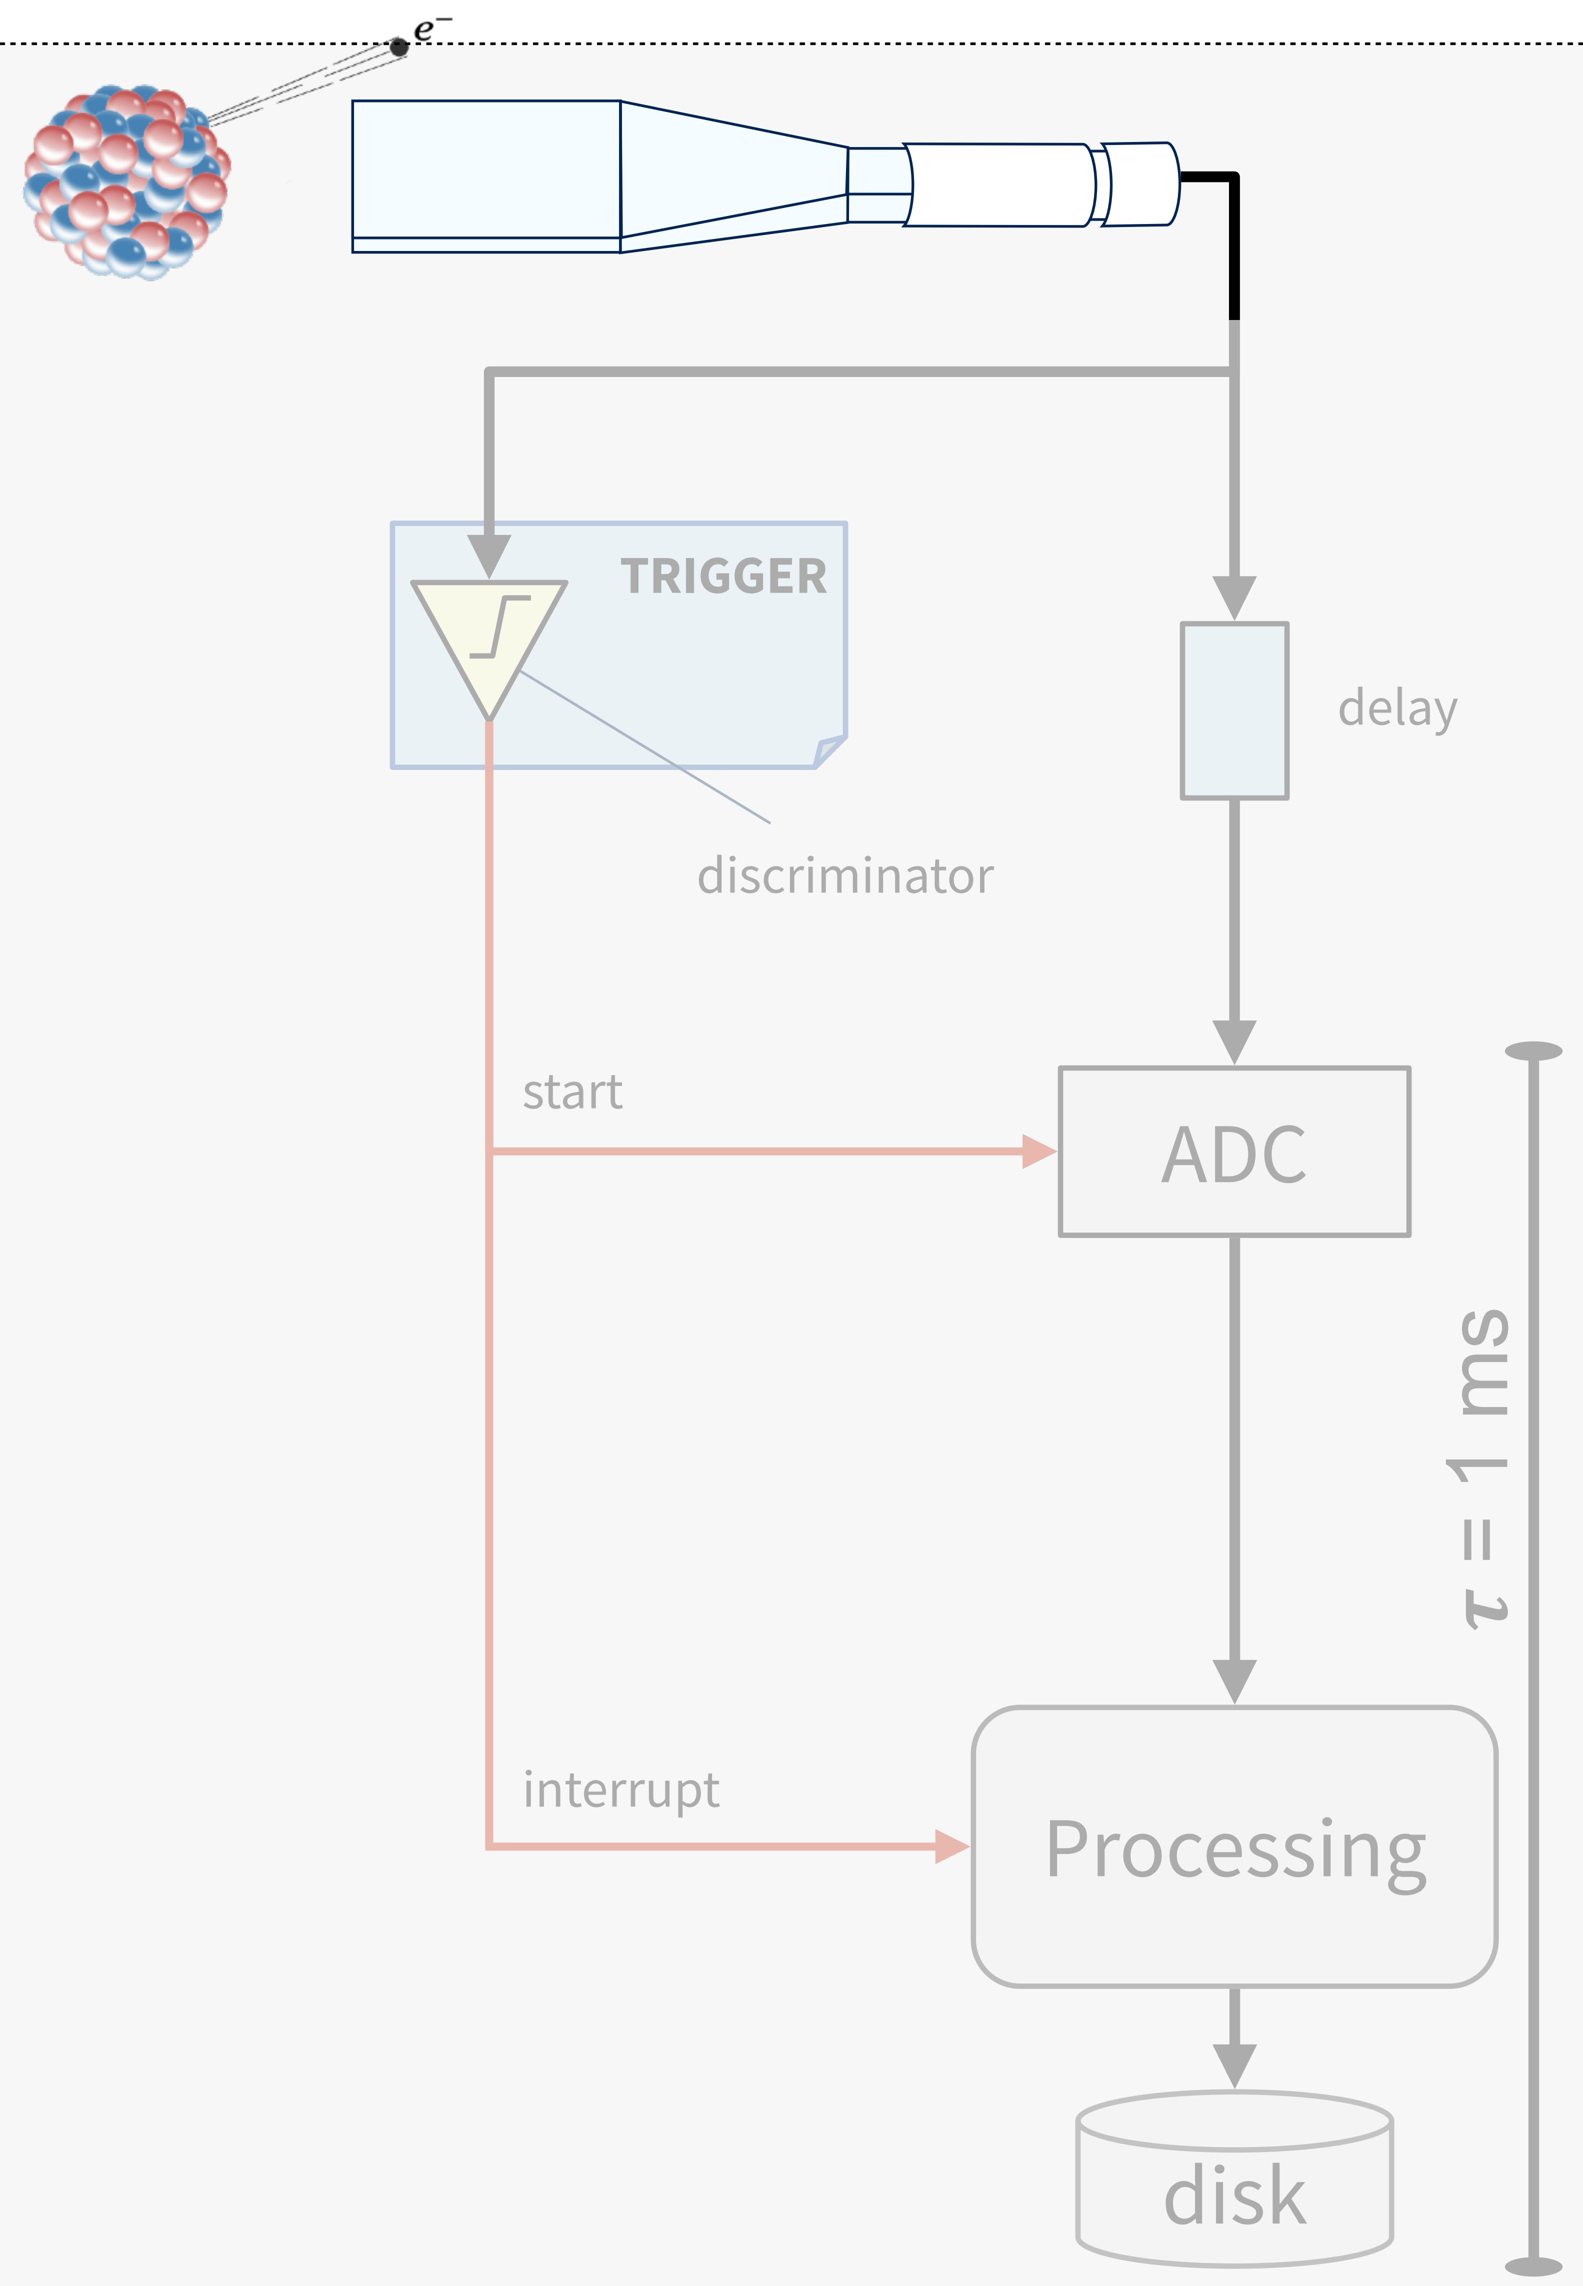
- E.g.: beta decay studies

A physics trigger is needed

- **Discriminator**: generates an output digital signal if amplitude of the input pulse is greater than a given threshold

NB: delay introduced to compensate for the **trigger latency**

- Signal split in trigger and data paths



Basic DAQ: "real" trigger

Events asynchronous and unpredictable

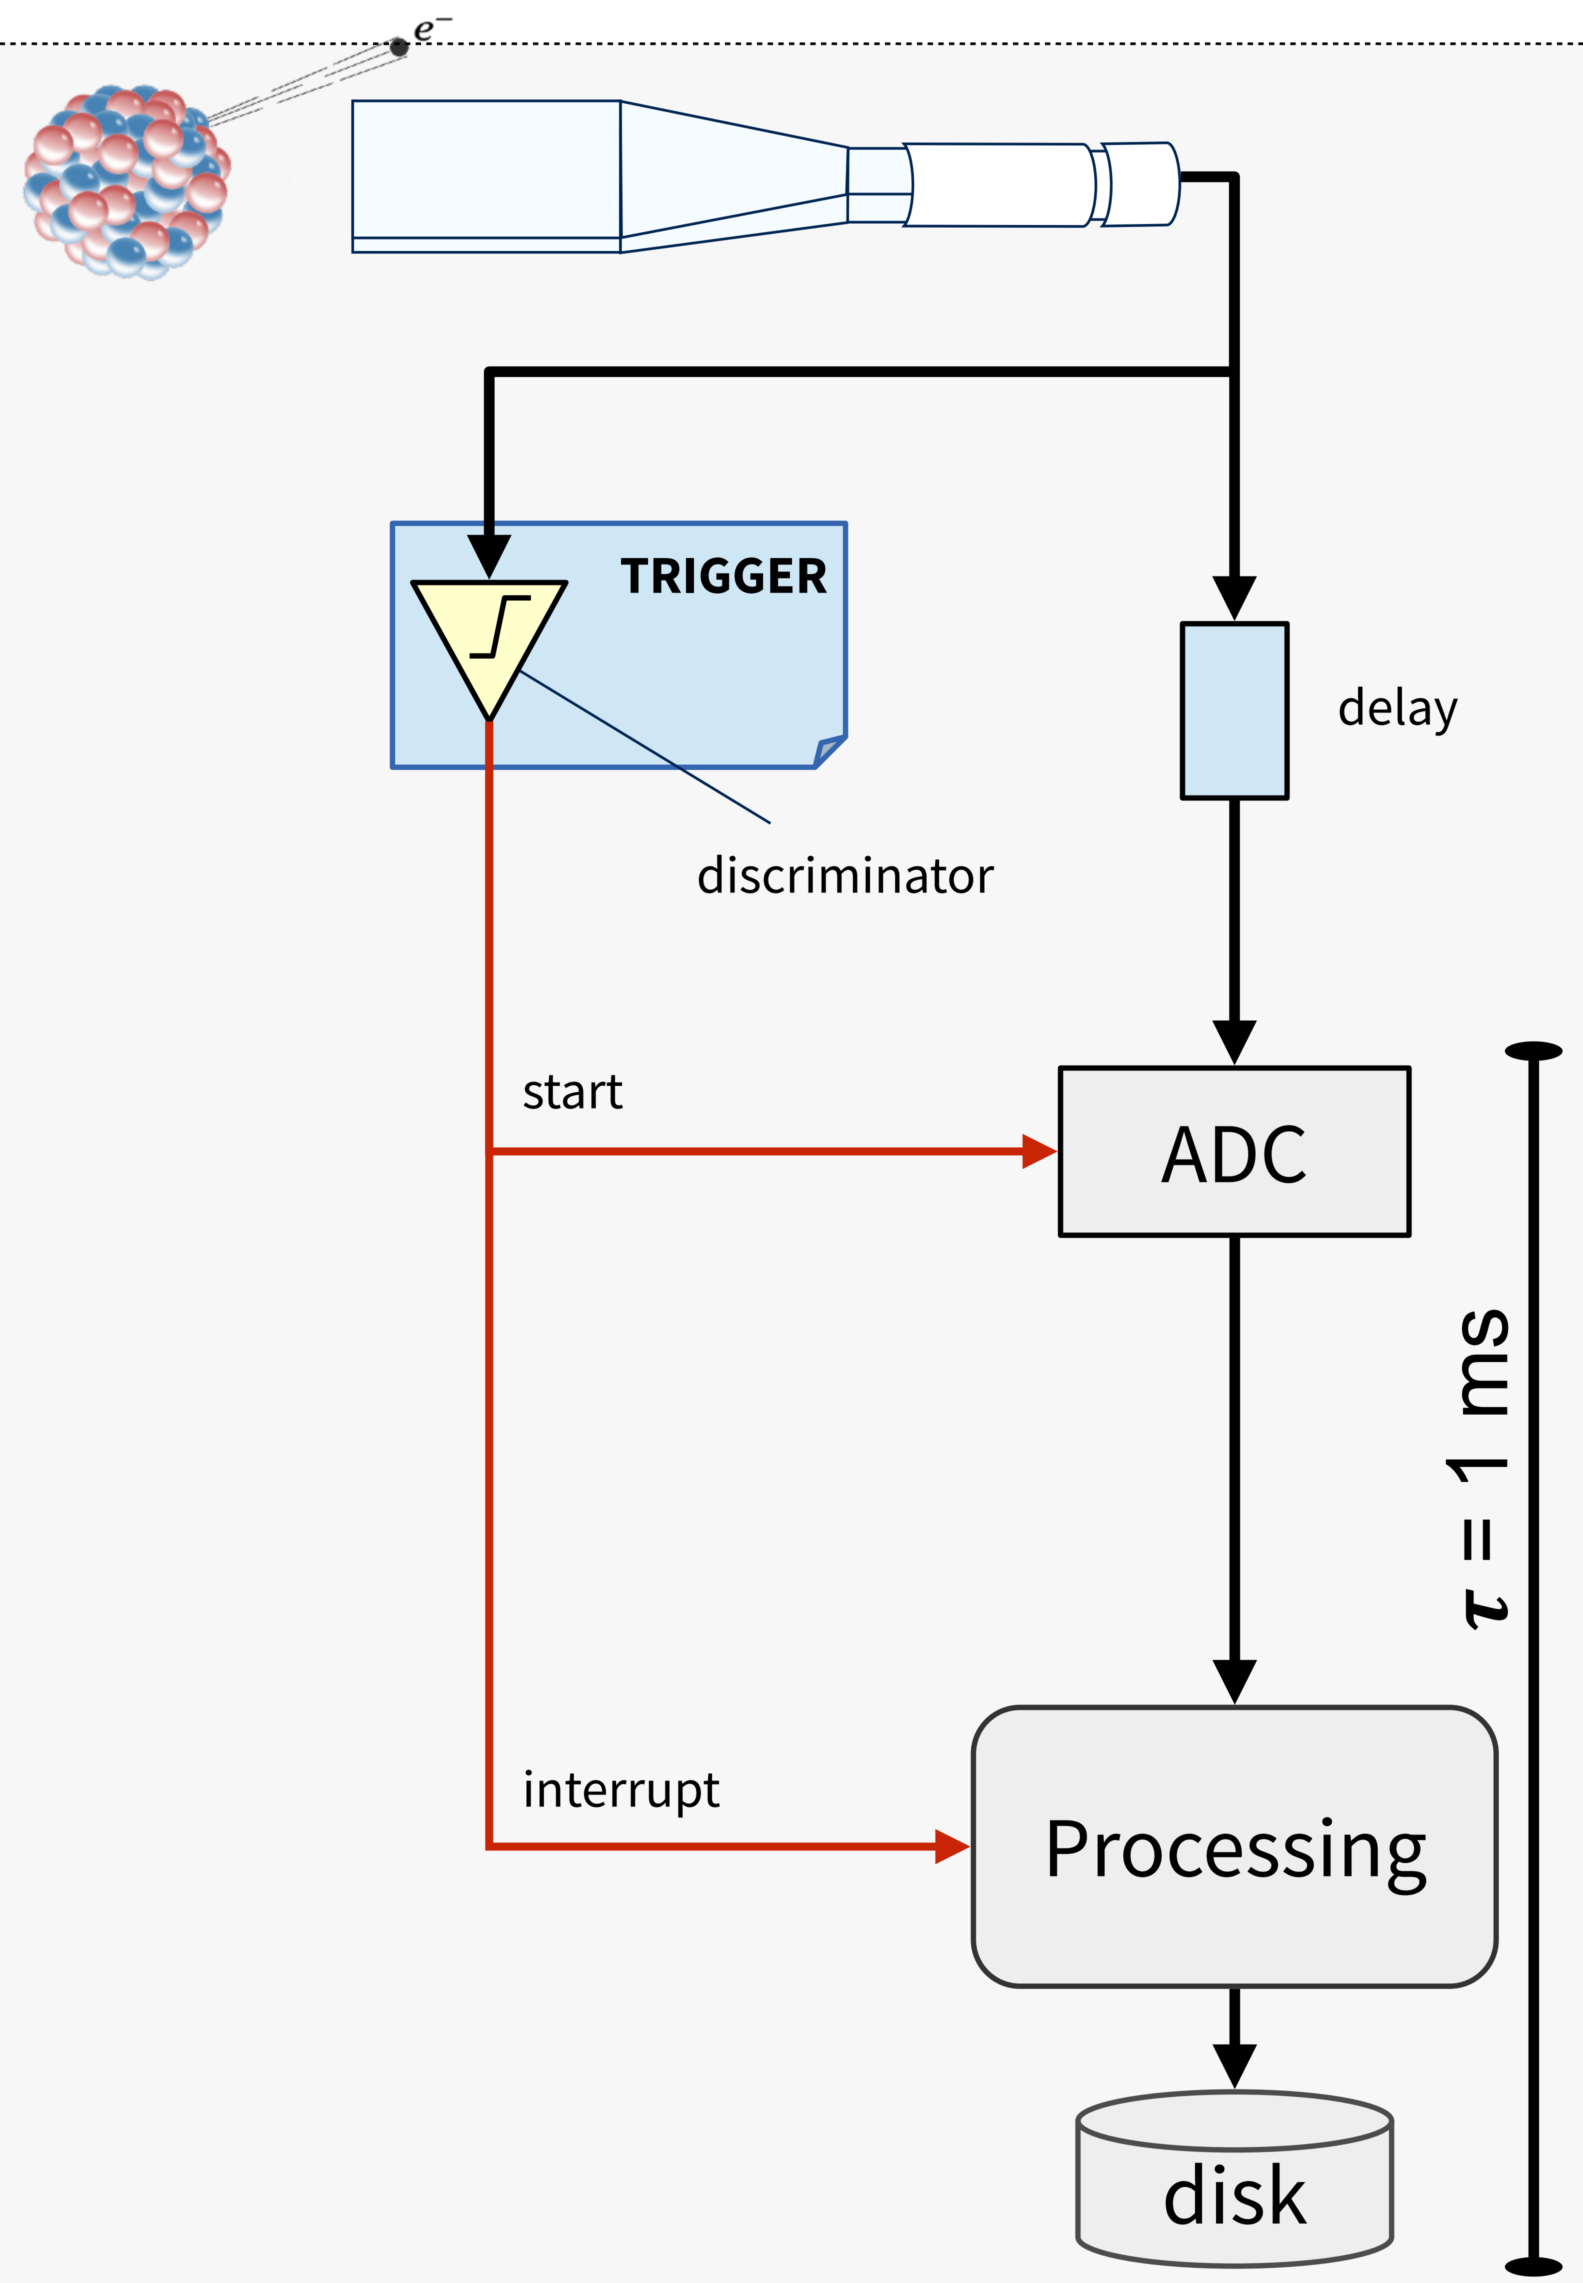
- E.g.: beta decay studies

A physics trigger is needed

- **Discriminator**: generates an output digital signal if amplitude of the input pulse is greater than a given threshold

NB: delay introduced to compensate for the **trigger latency**

- Signal split in trigger and data paths



Basic DAQ: “real” trigger

Events asynchronous and unpredictable

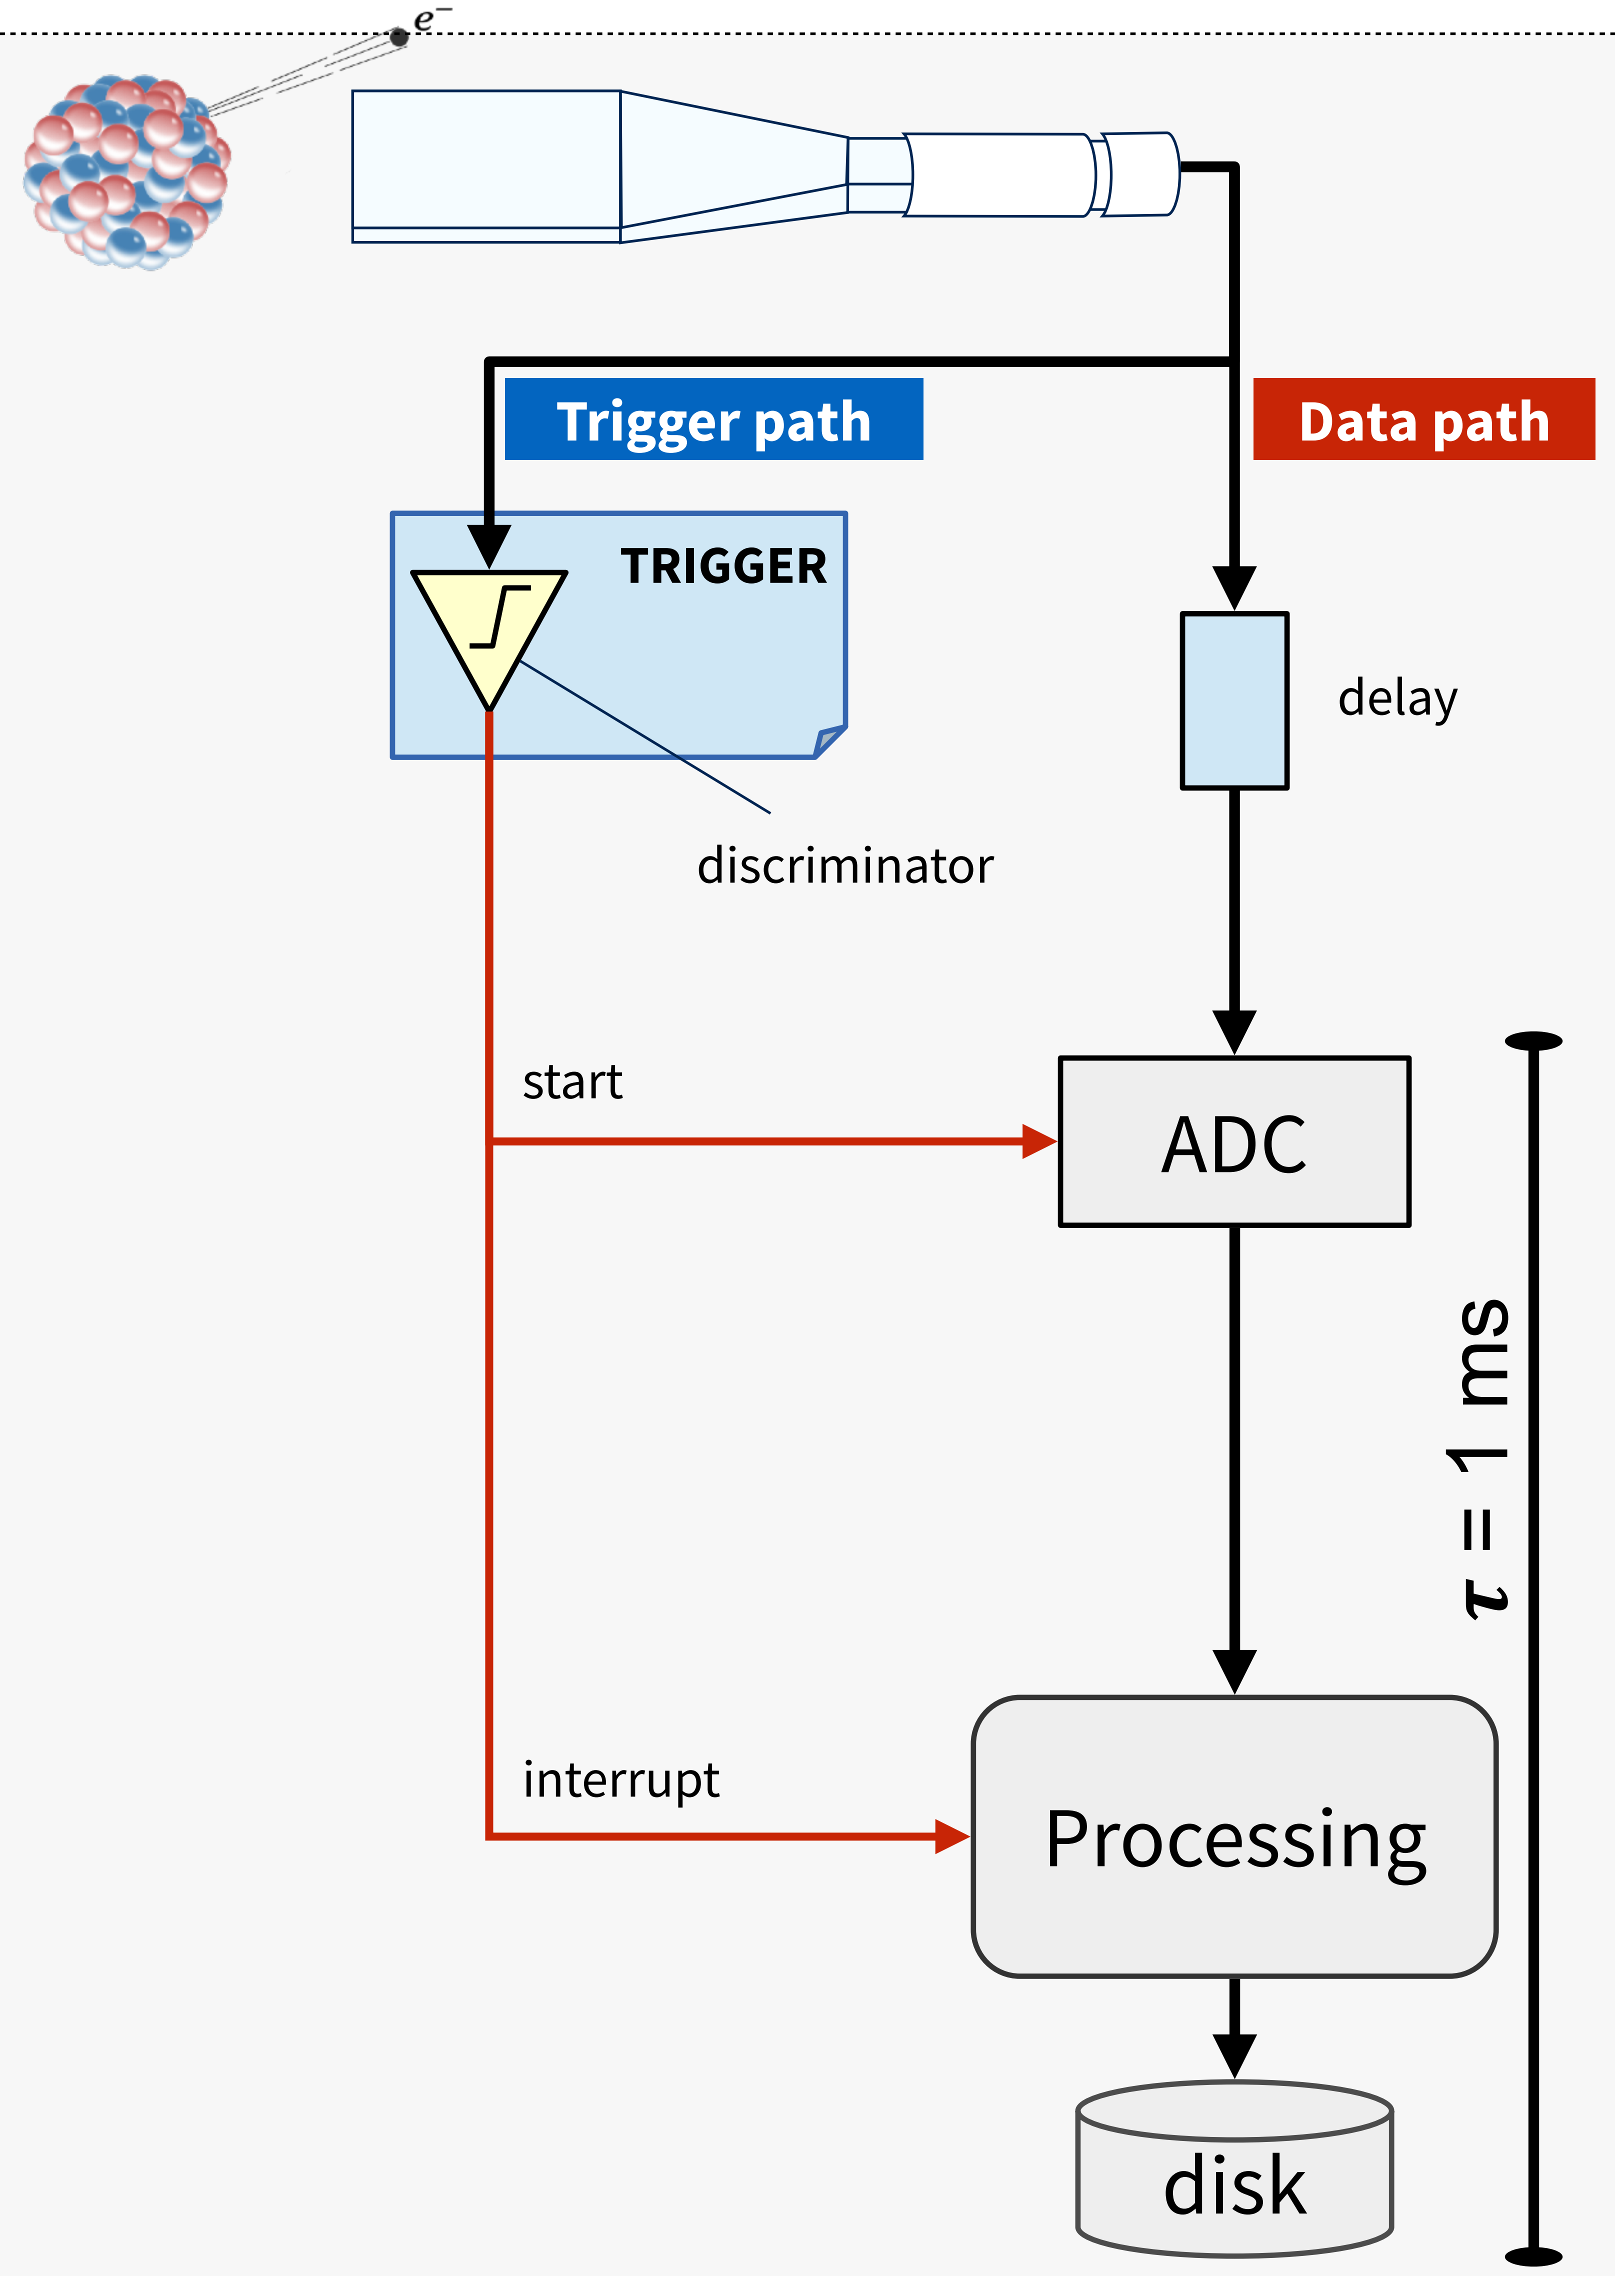
- E.g.: beta decay studies

A physics trigger is needed

- **Discriminator**: generates an output digital signal if amplitude of the input pulse is greater than a given threshold

NB: delay introduced to compensate for the **trigger latency**

- Signal split in trigger and data paths



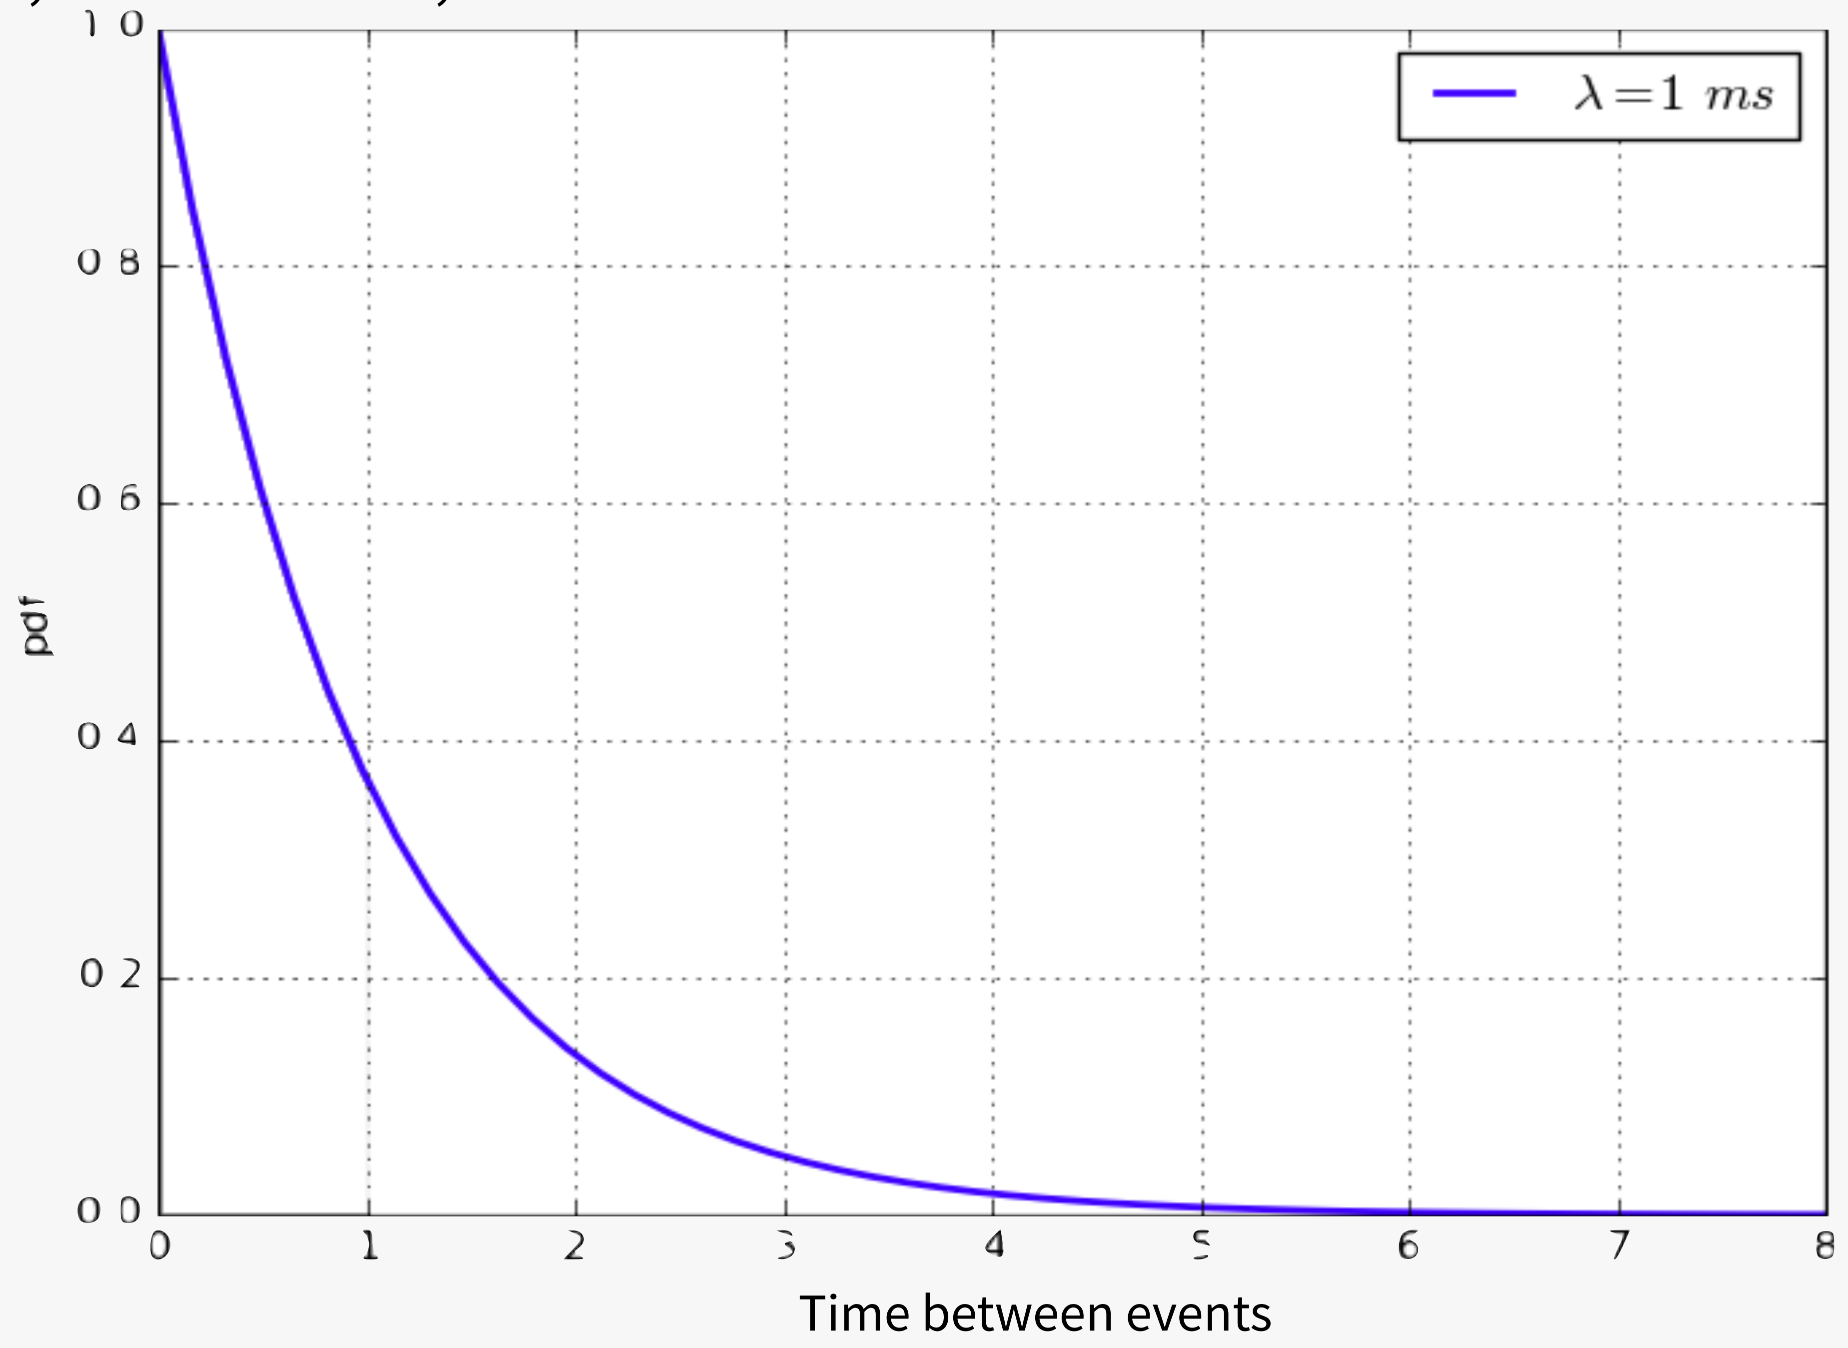
Basic DAQ: “real” trigger

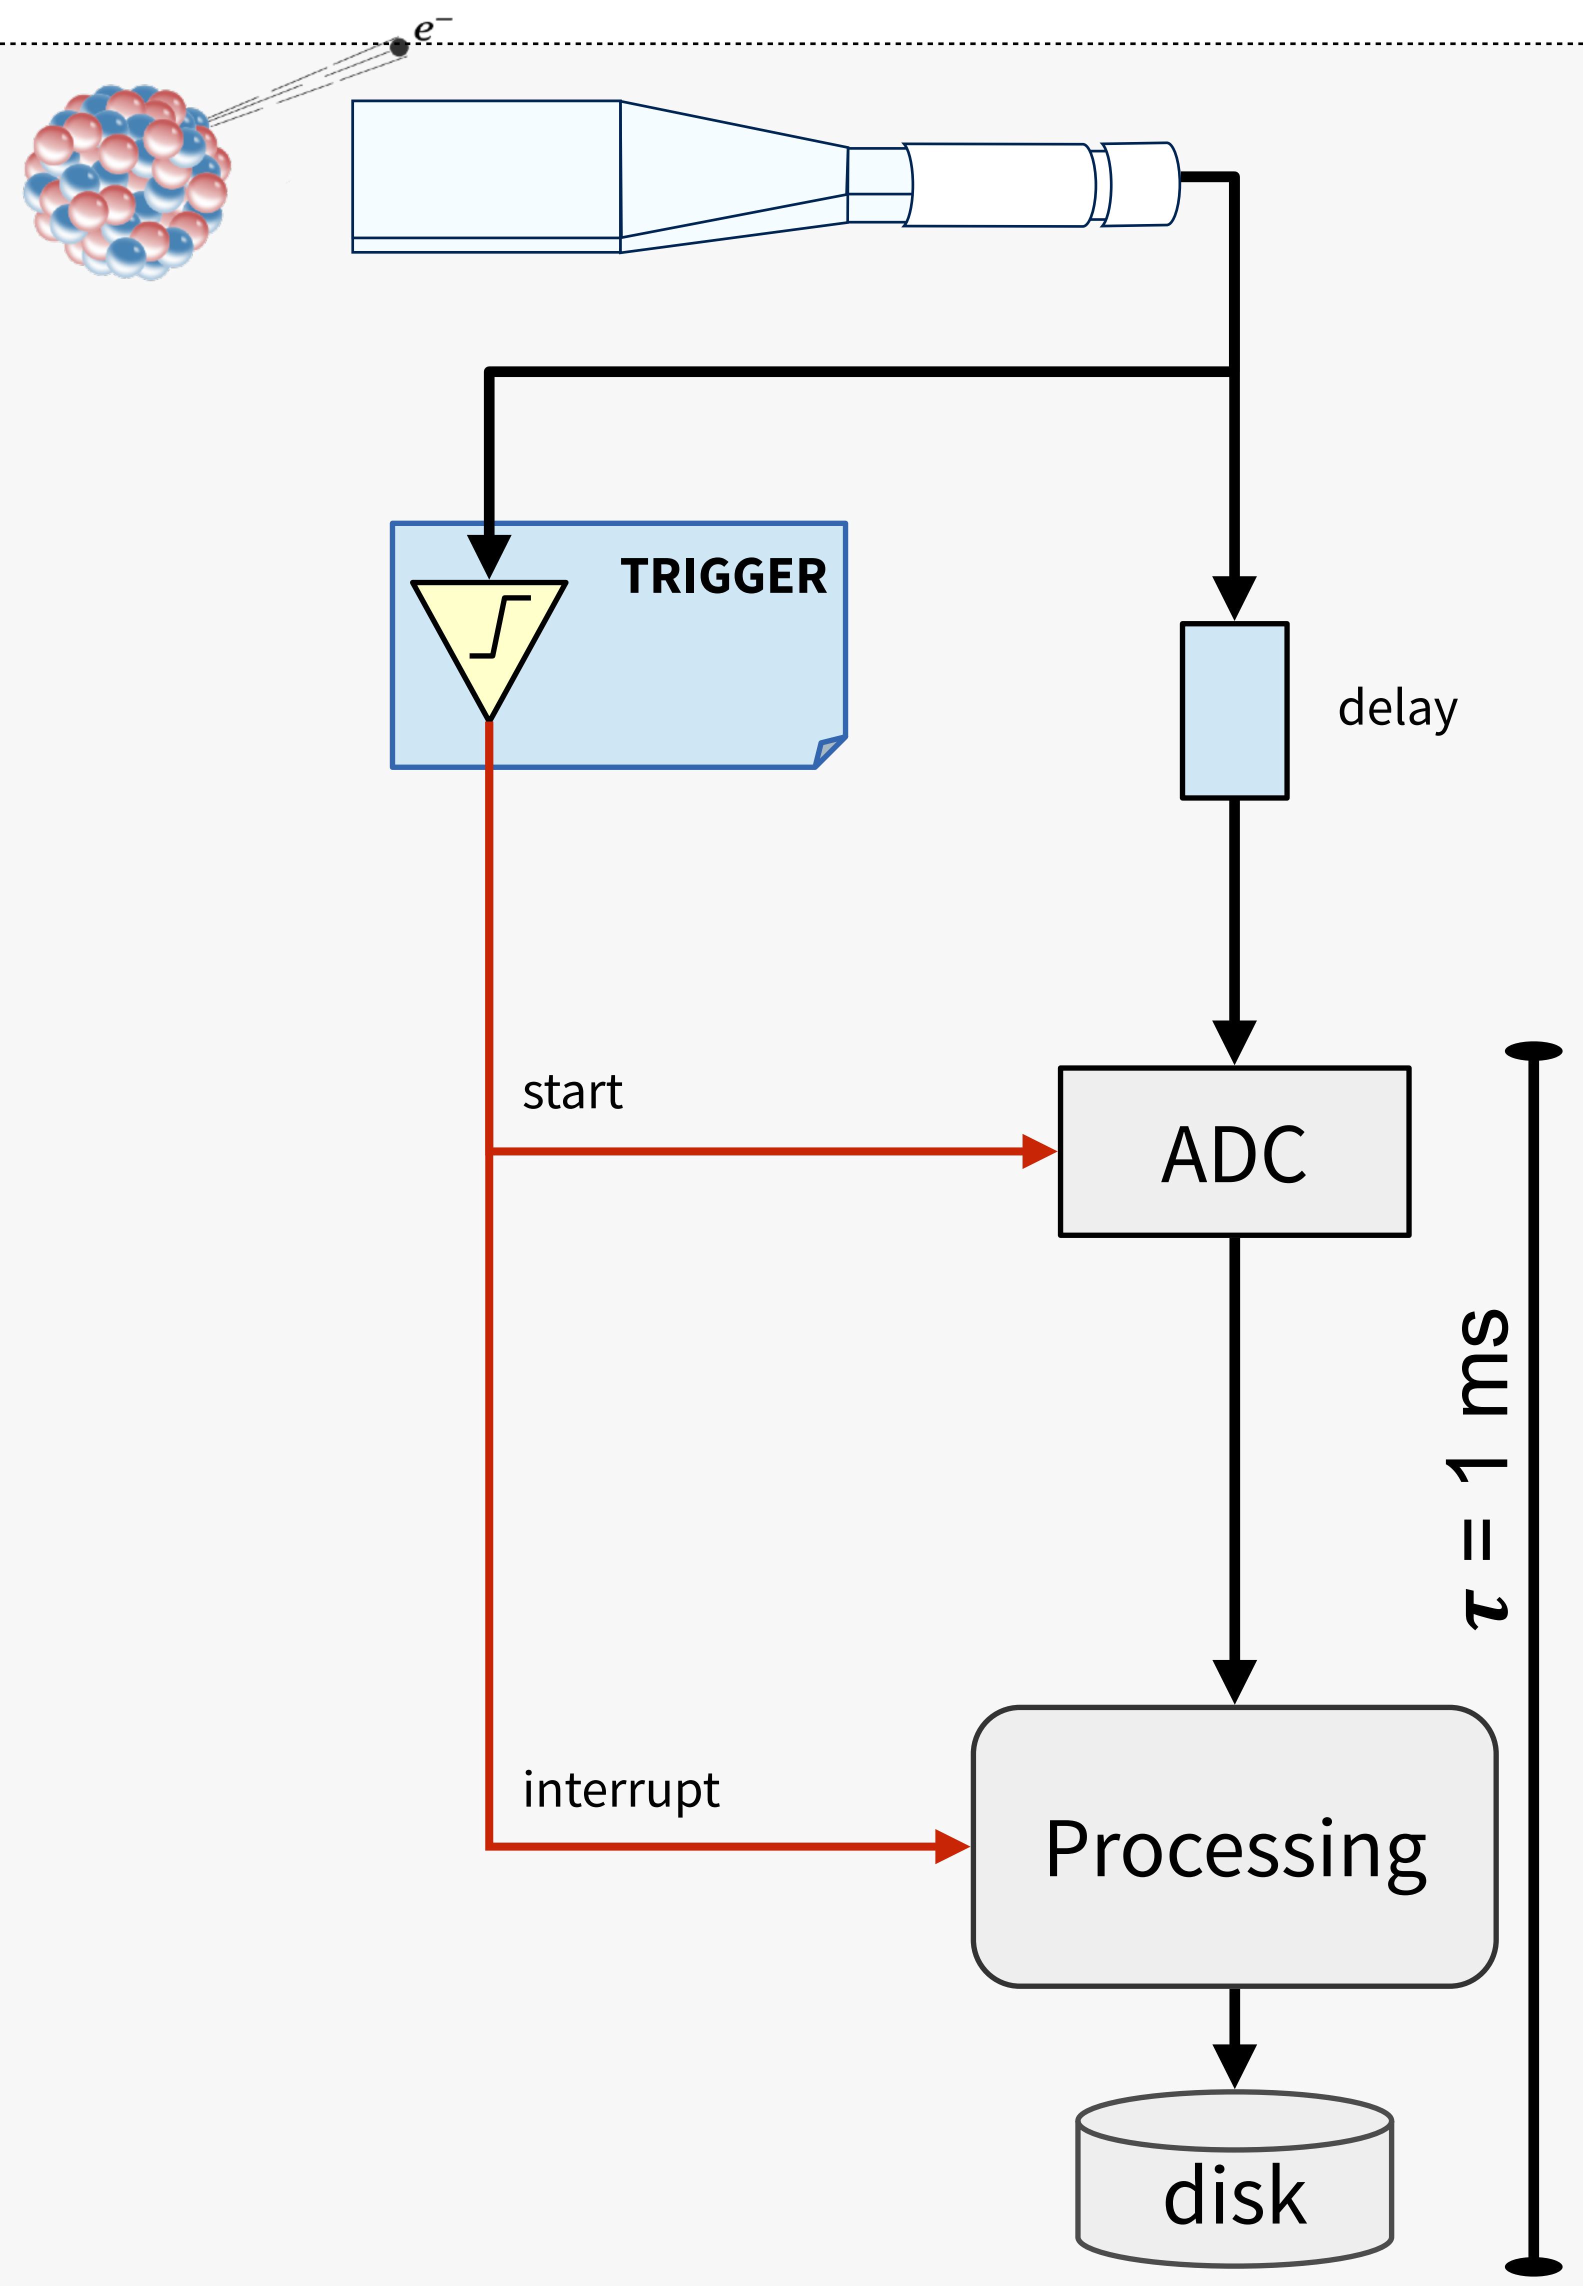
Stochastic process

- Fluctuations in time between events

Let's assume for example

- physics rate $f = 1$ kHz, i.e. $\lambda = 1$ ms
- and, as before, $\tau = 1$ ms





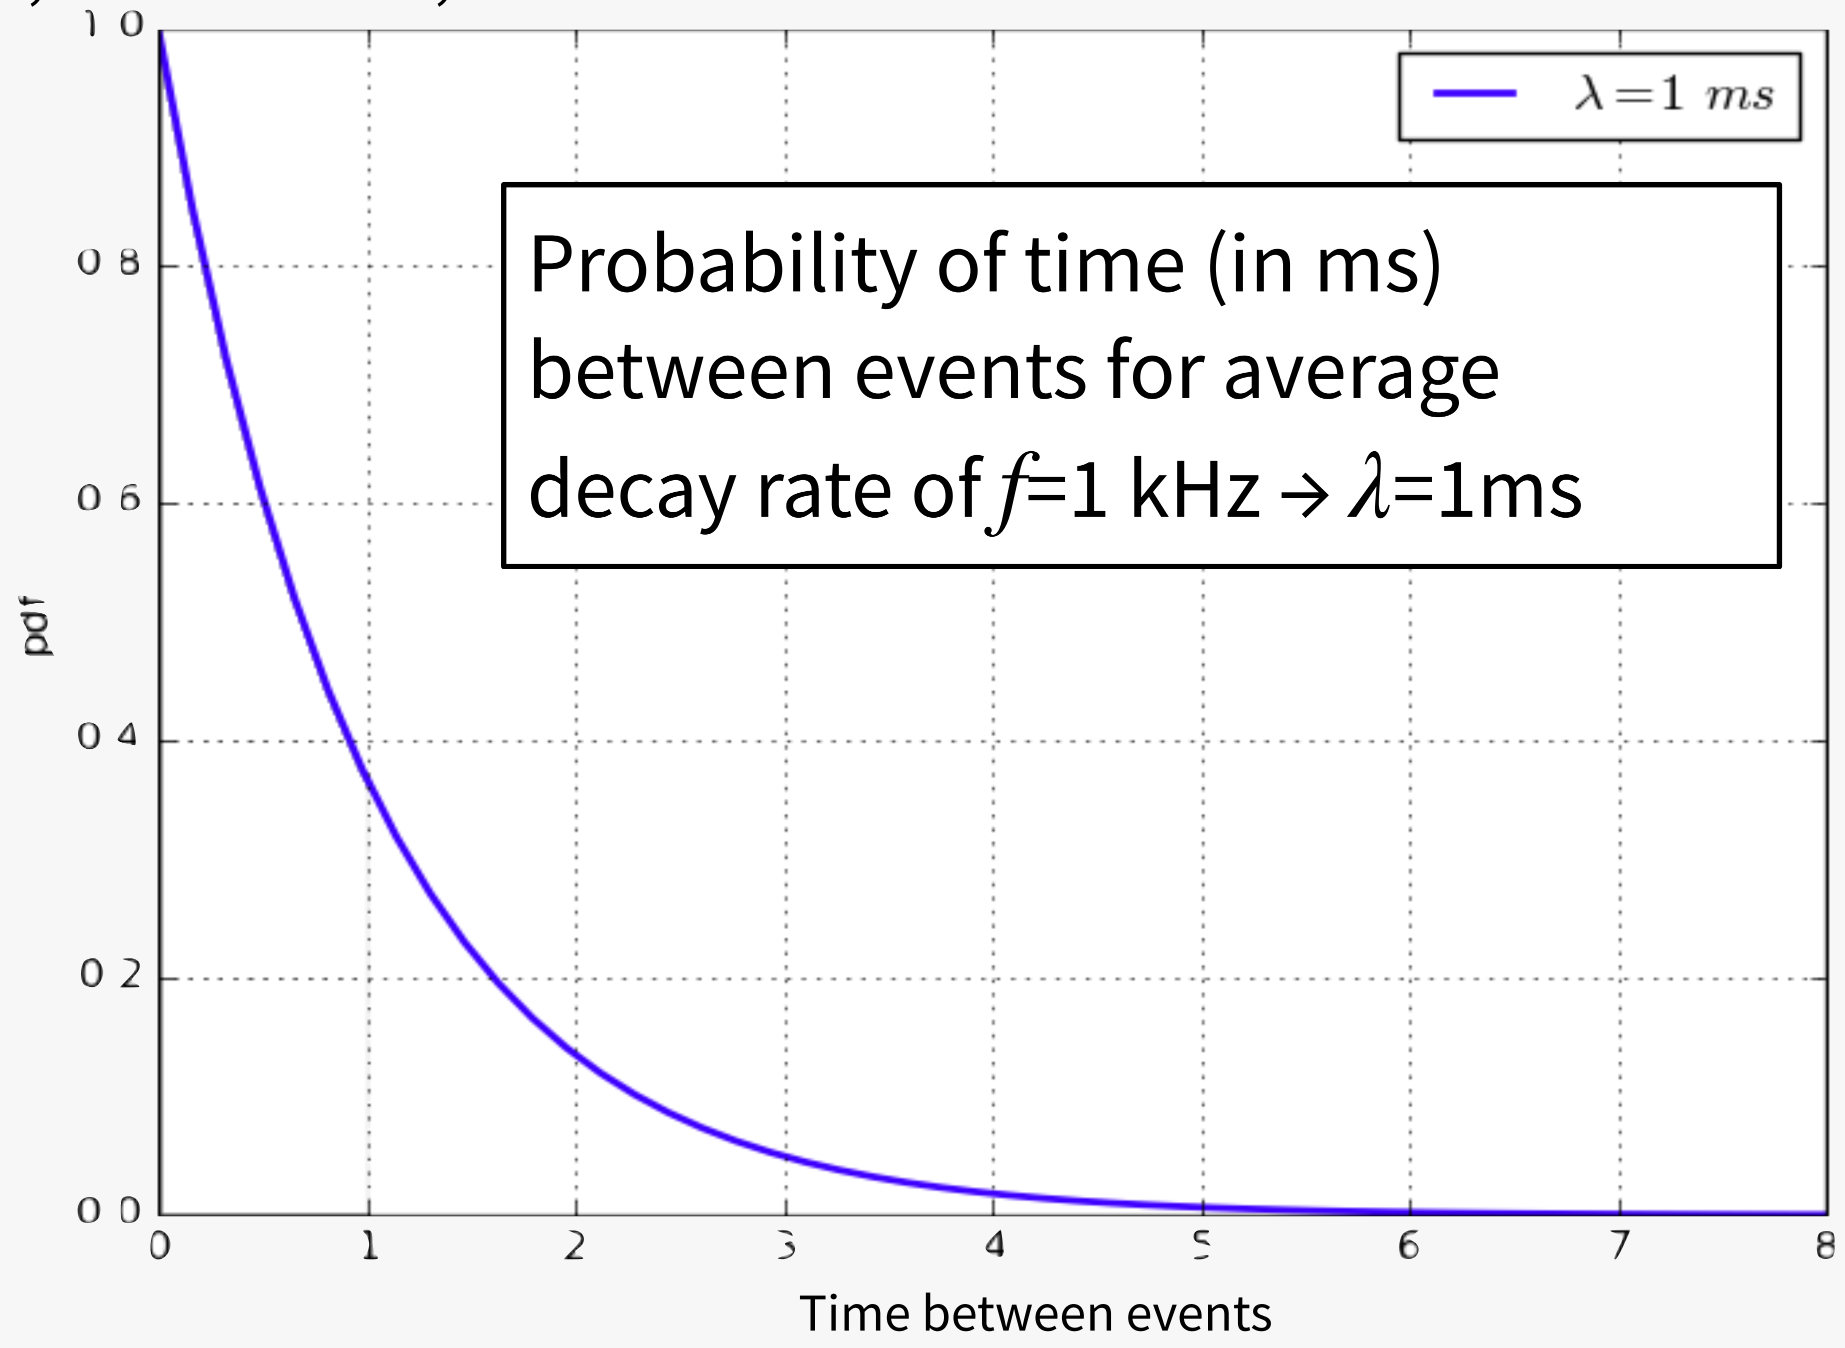
Basic DAQ: “real” trigger

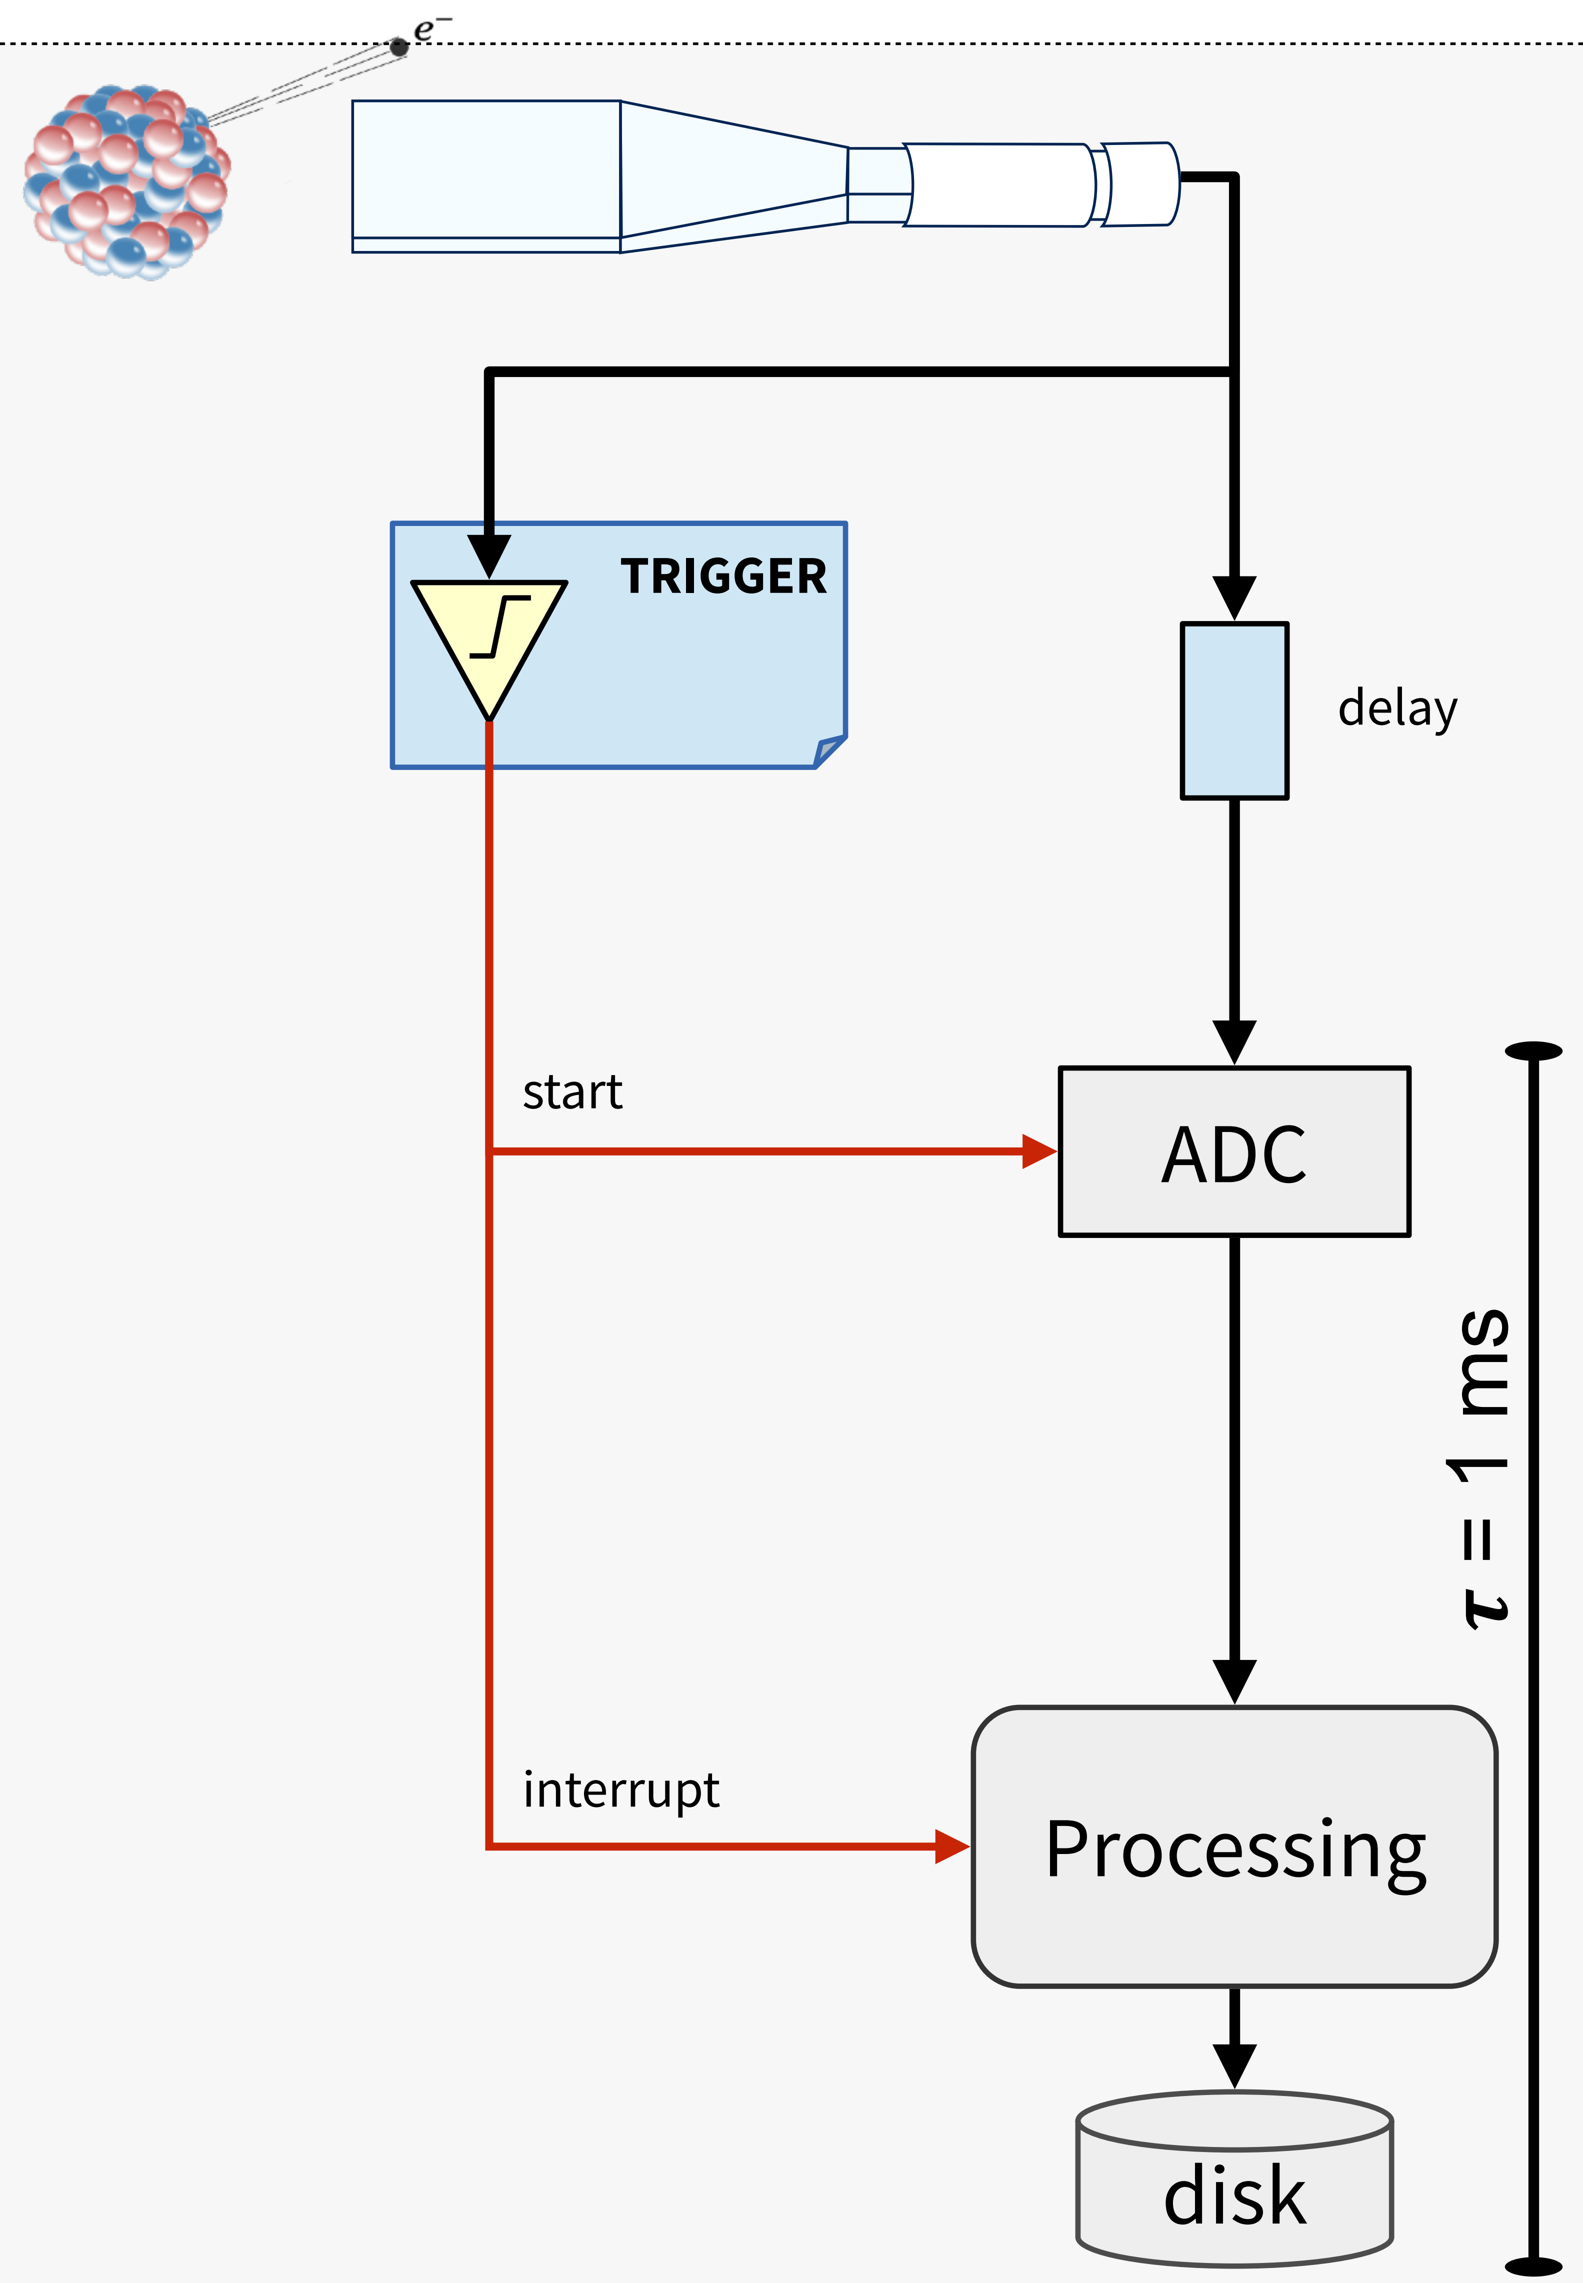
Stochastic process

- Fluctuations in time between events

Let's assume for example

- physics rate f = 1 kHz, i.e. λ = 1 ms
- and, as before, τ = 1 ms





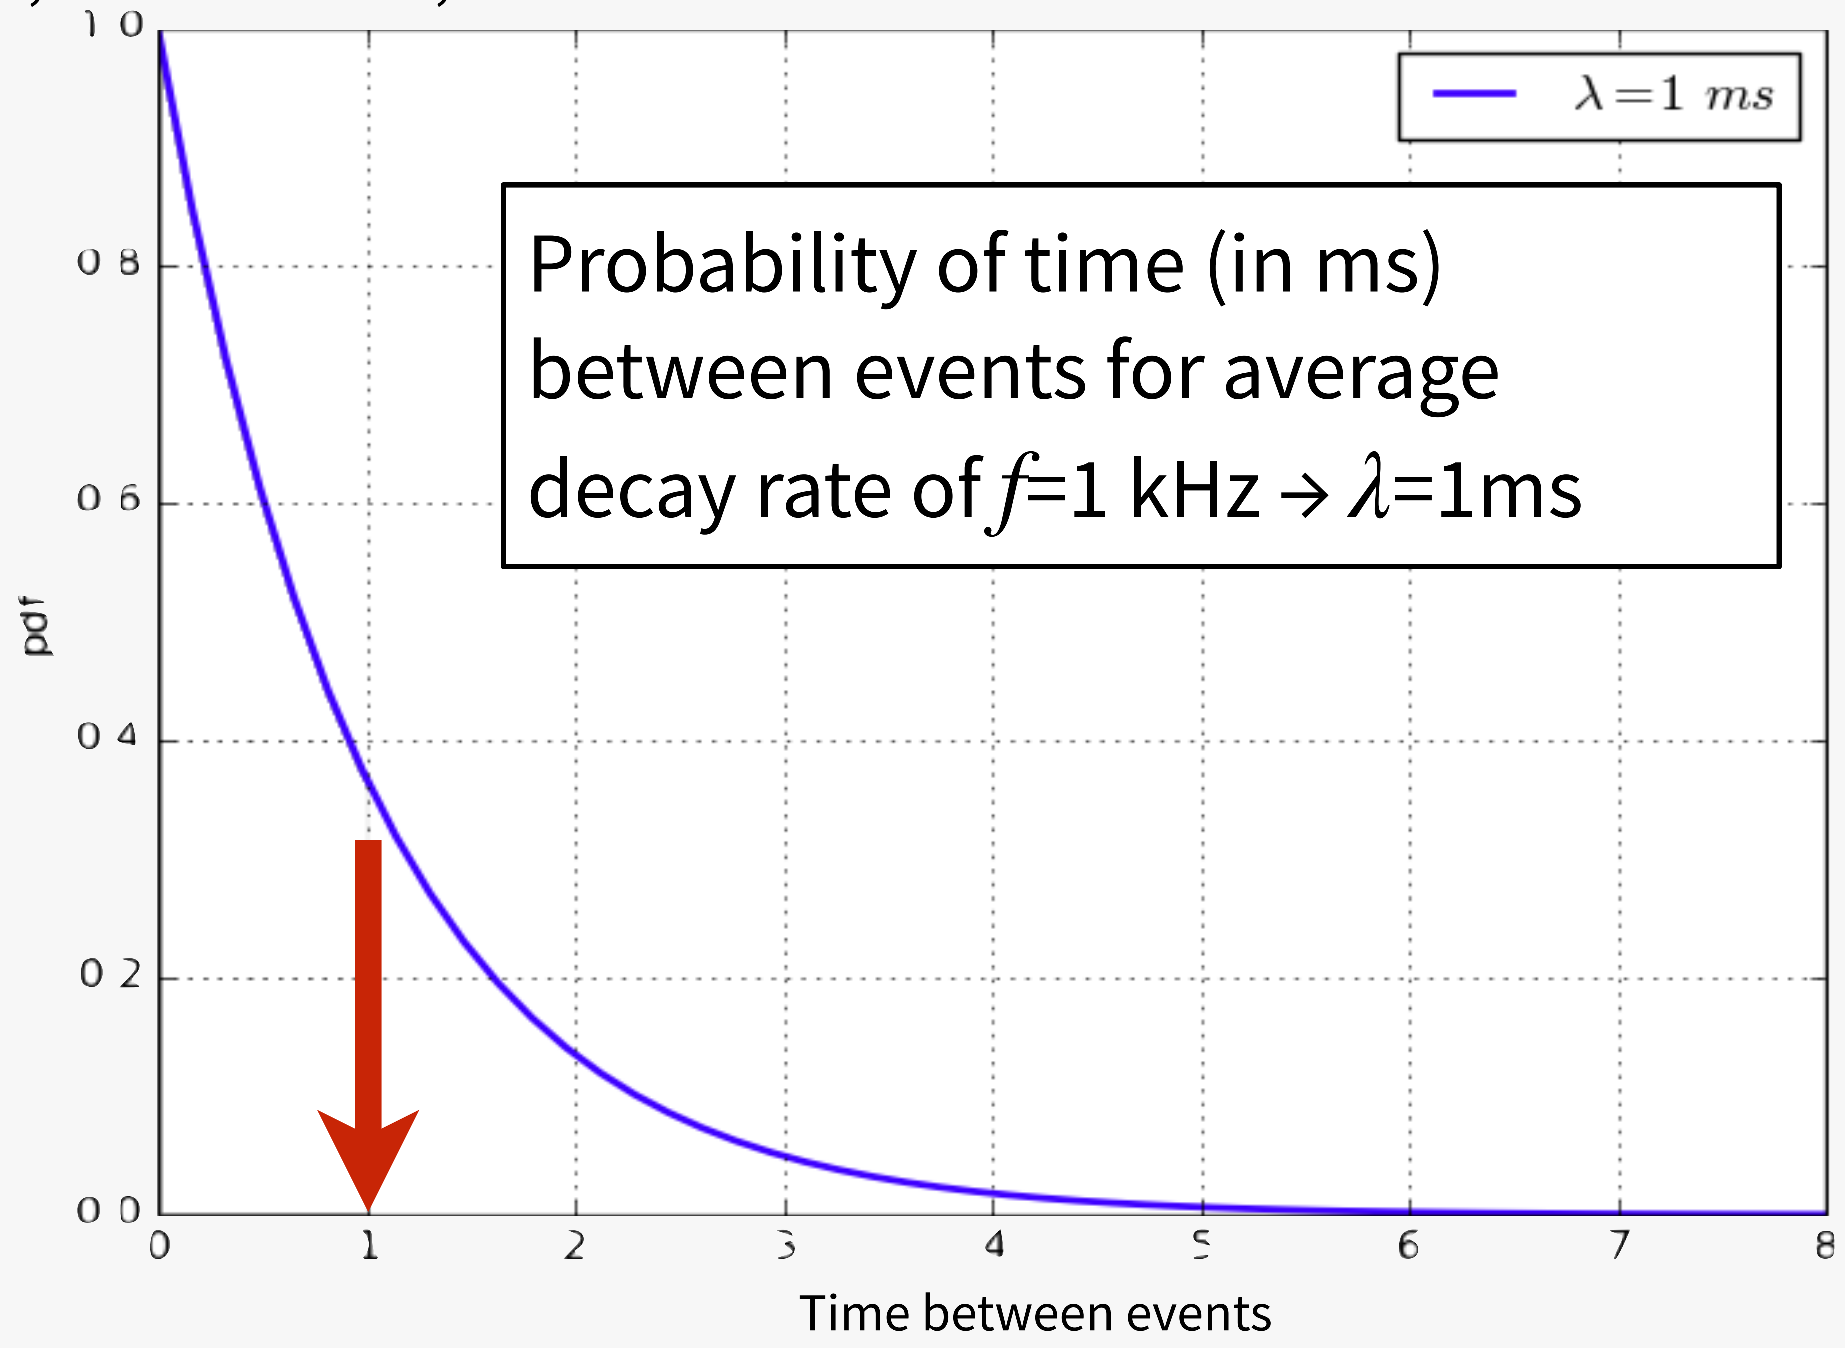
Basic DAQ: “real” trigger

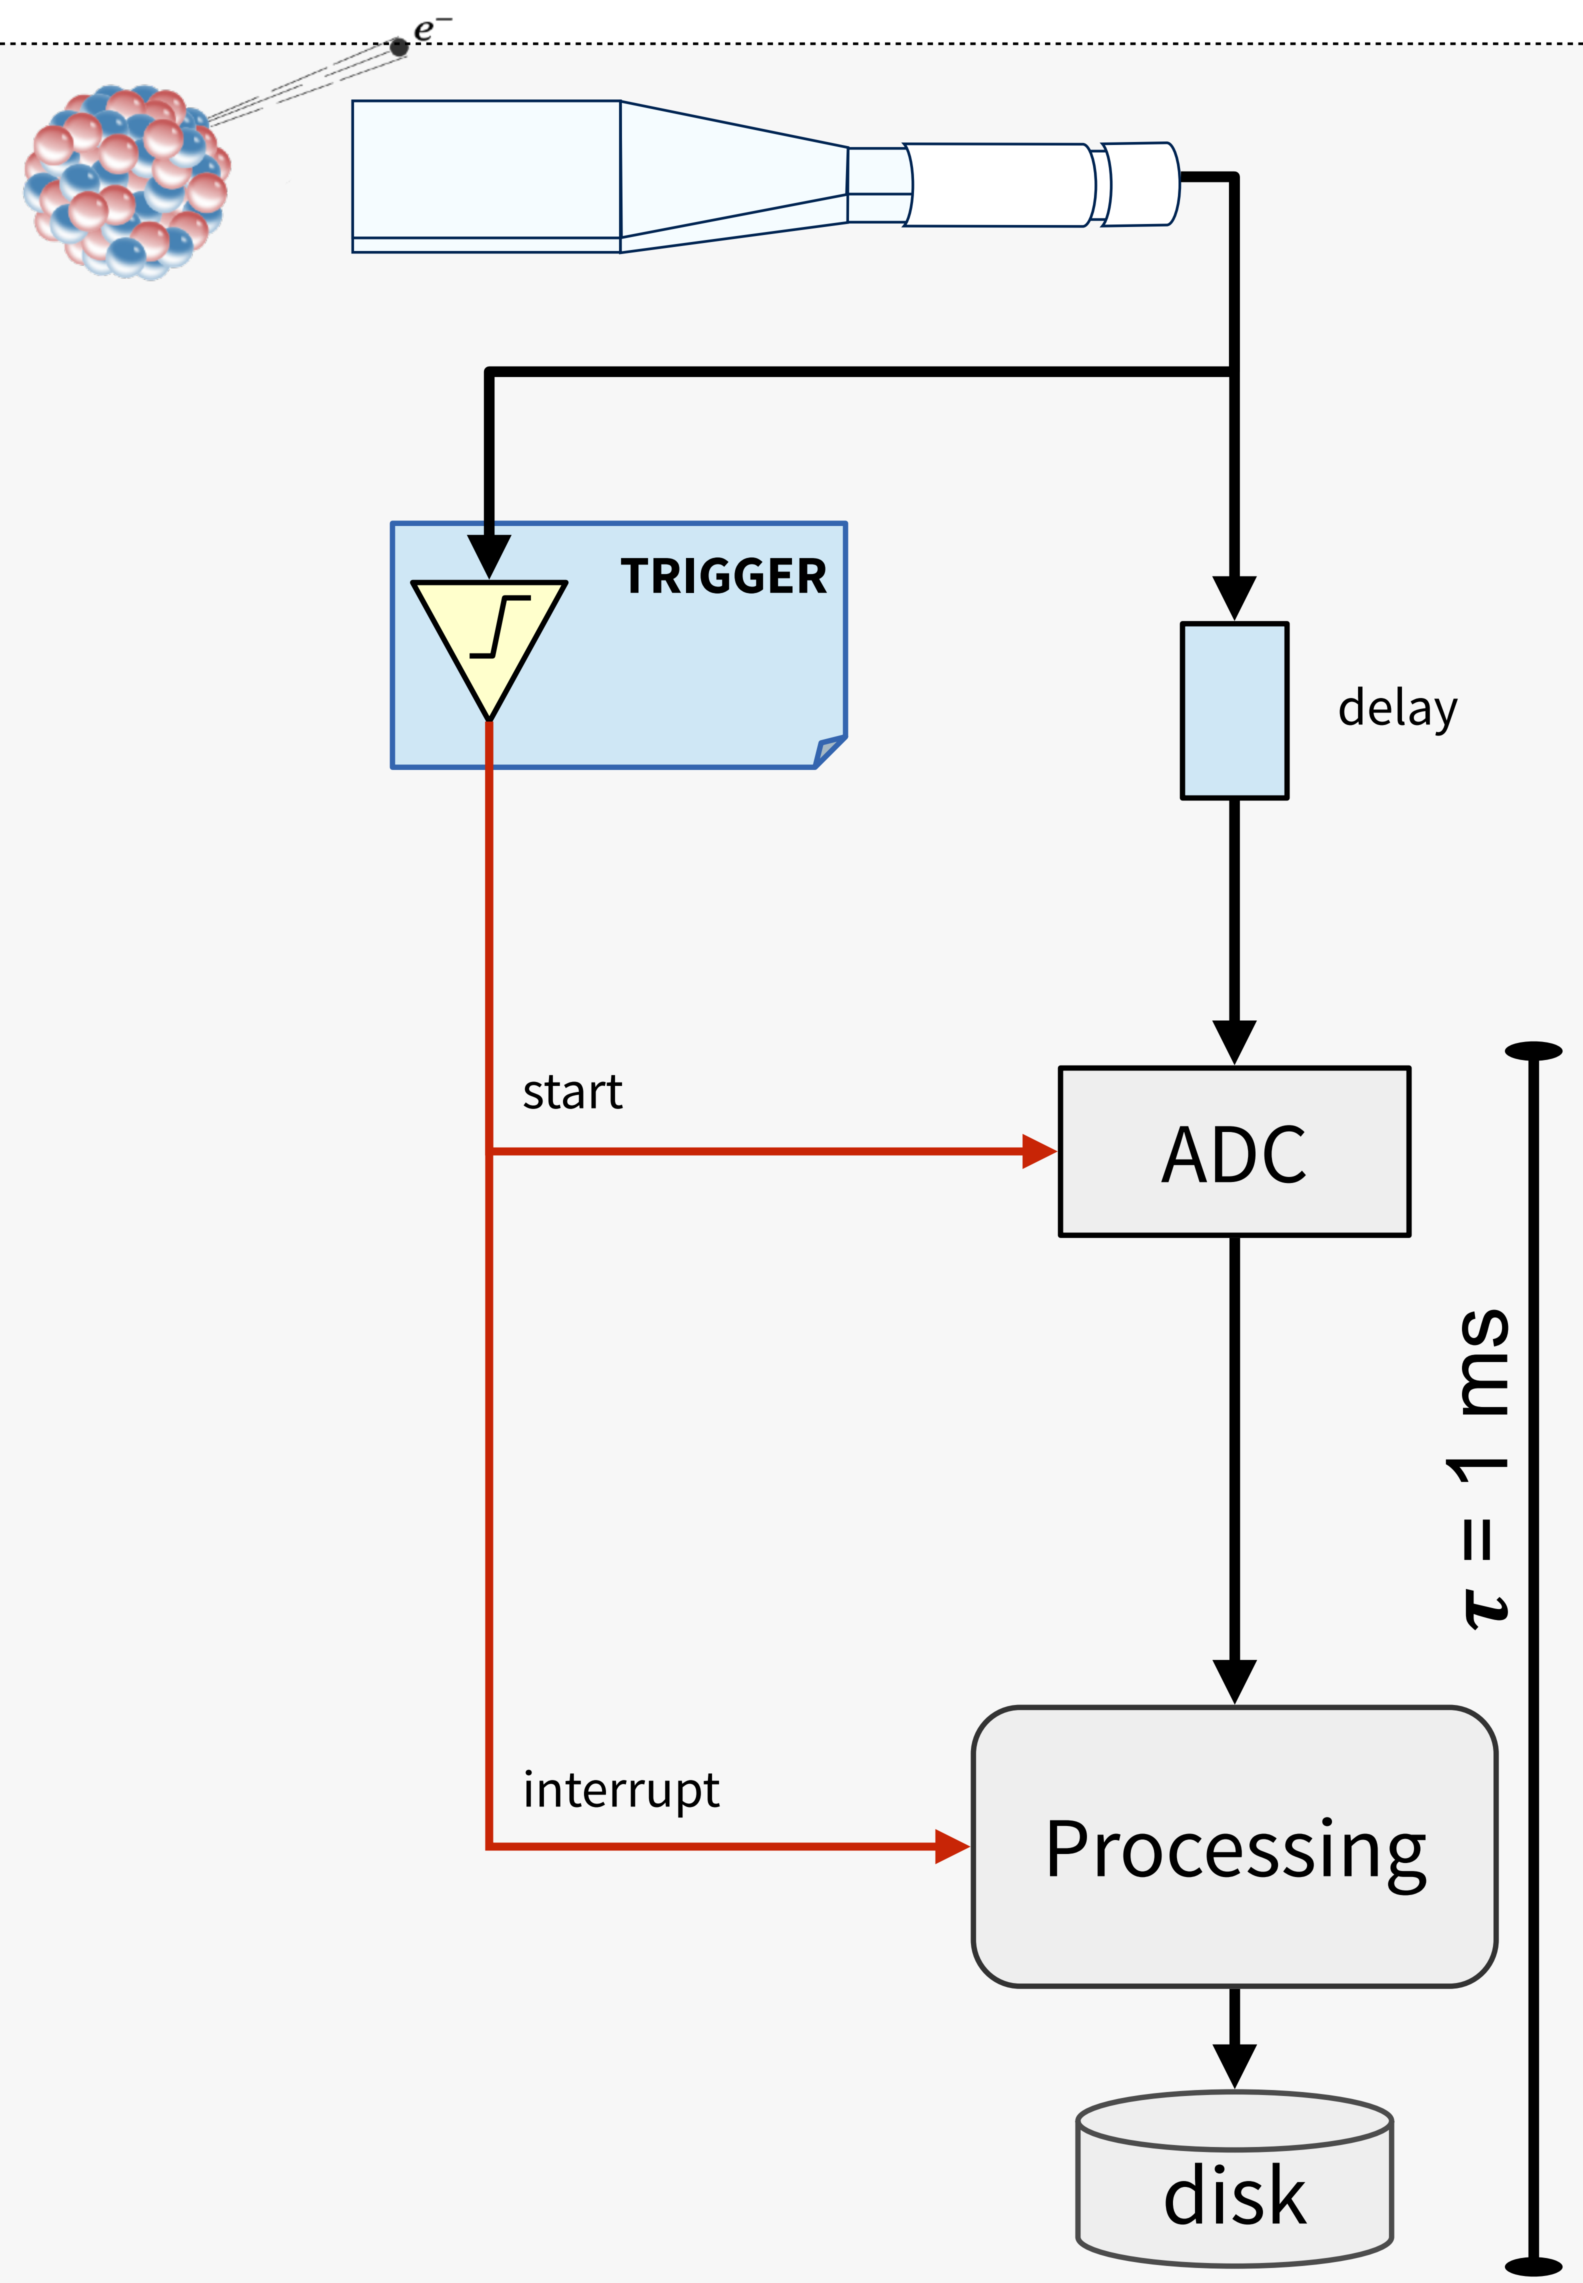
Stochastic process

- Fluctuations in time between events

Let's assume for example

- physics rate $f = 1$ kHz, i.e. $\lambda = 1$ ms
- and, as before, $\tau = 1$ ms





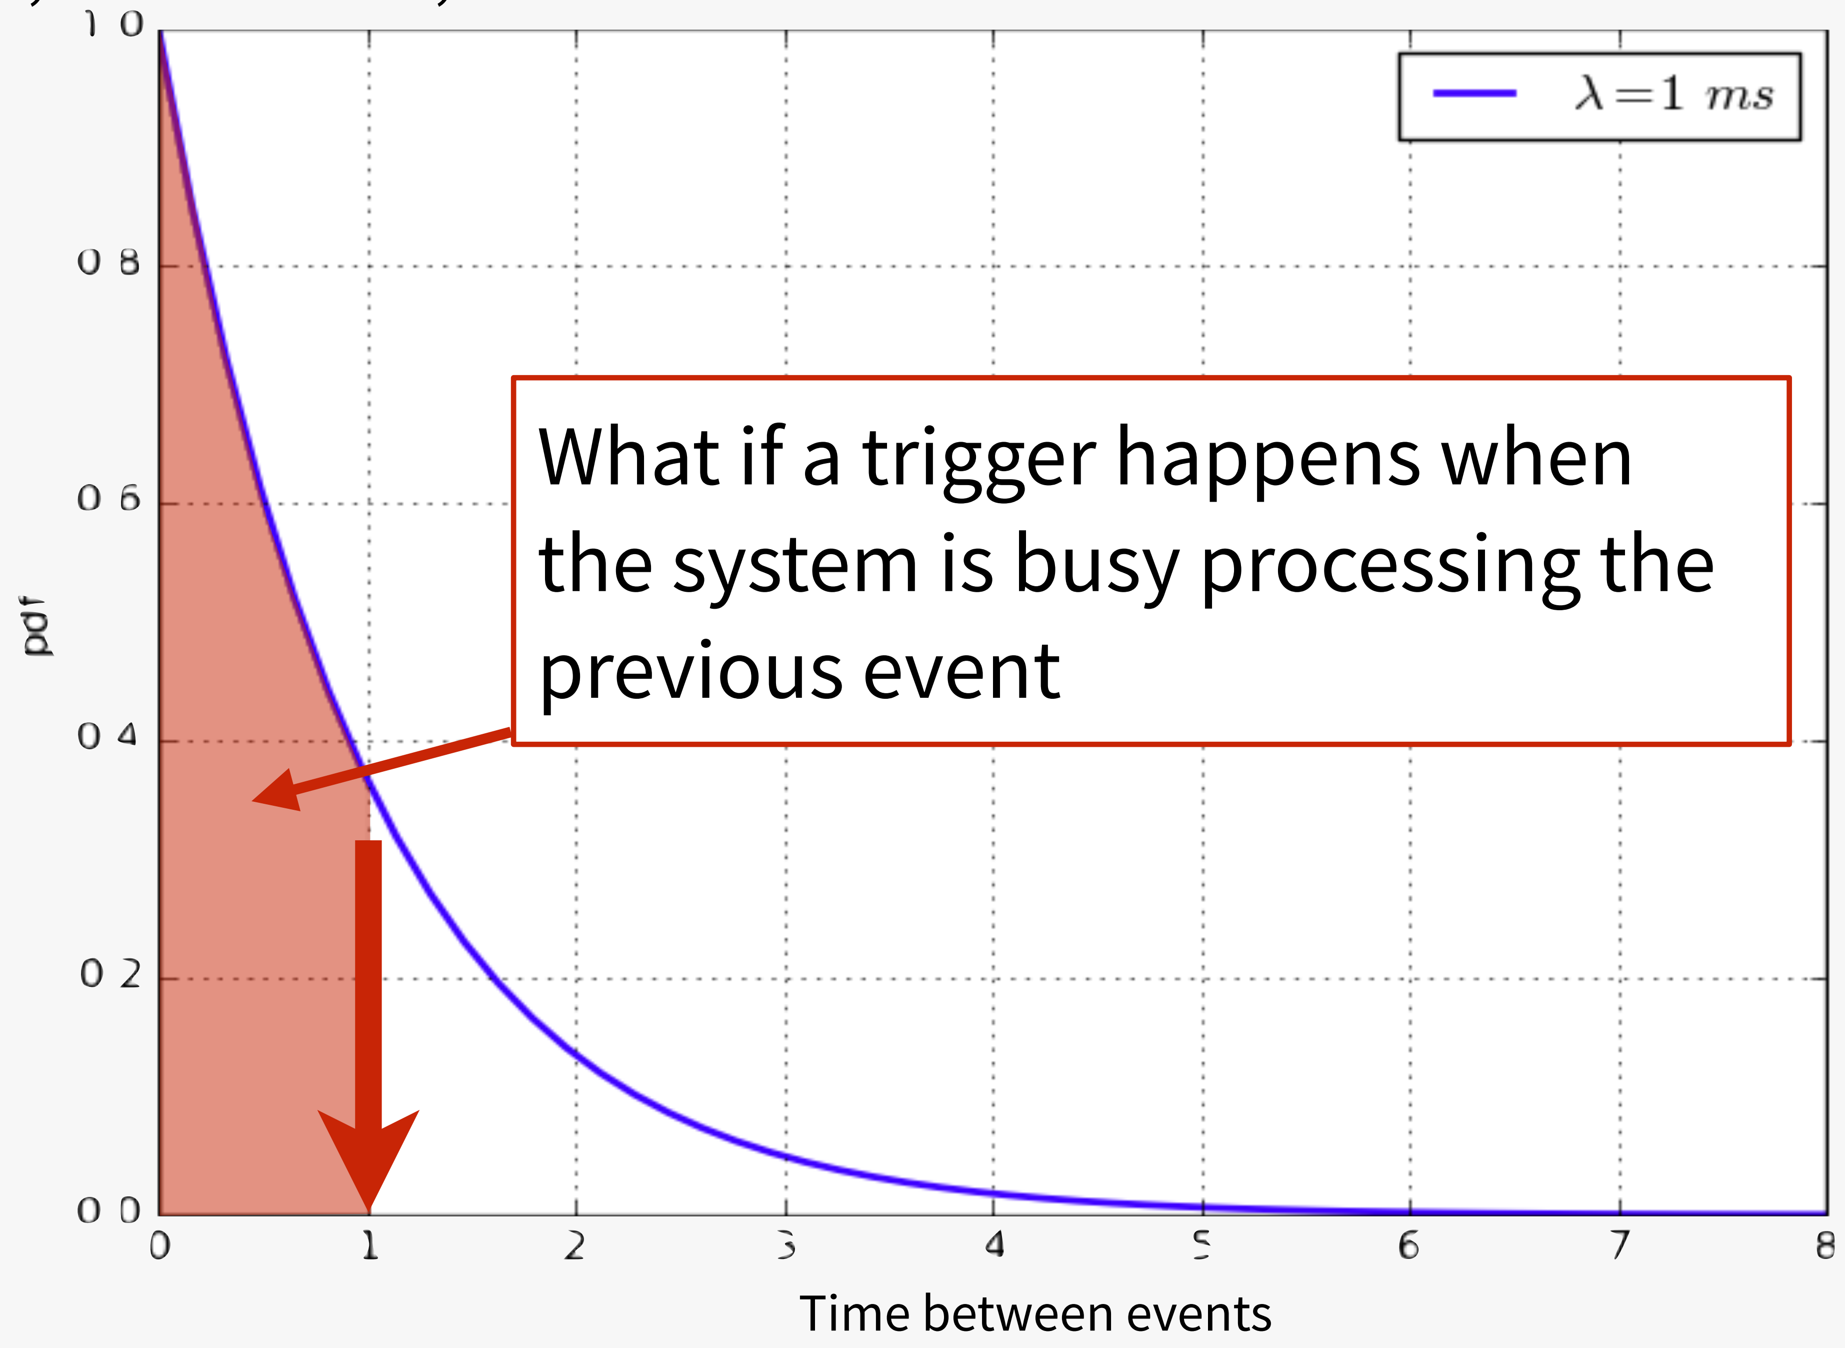
Basic DAQ: “real” trigger

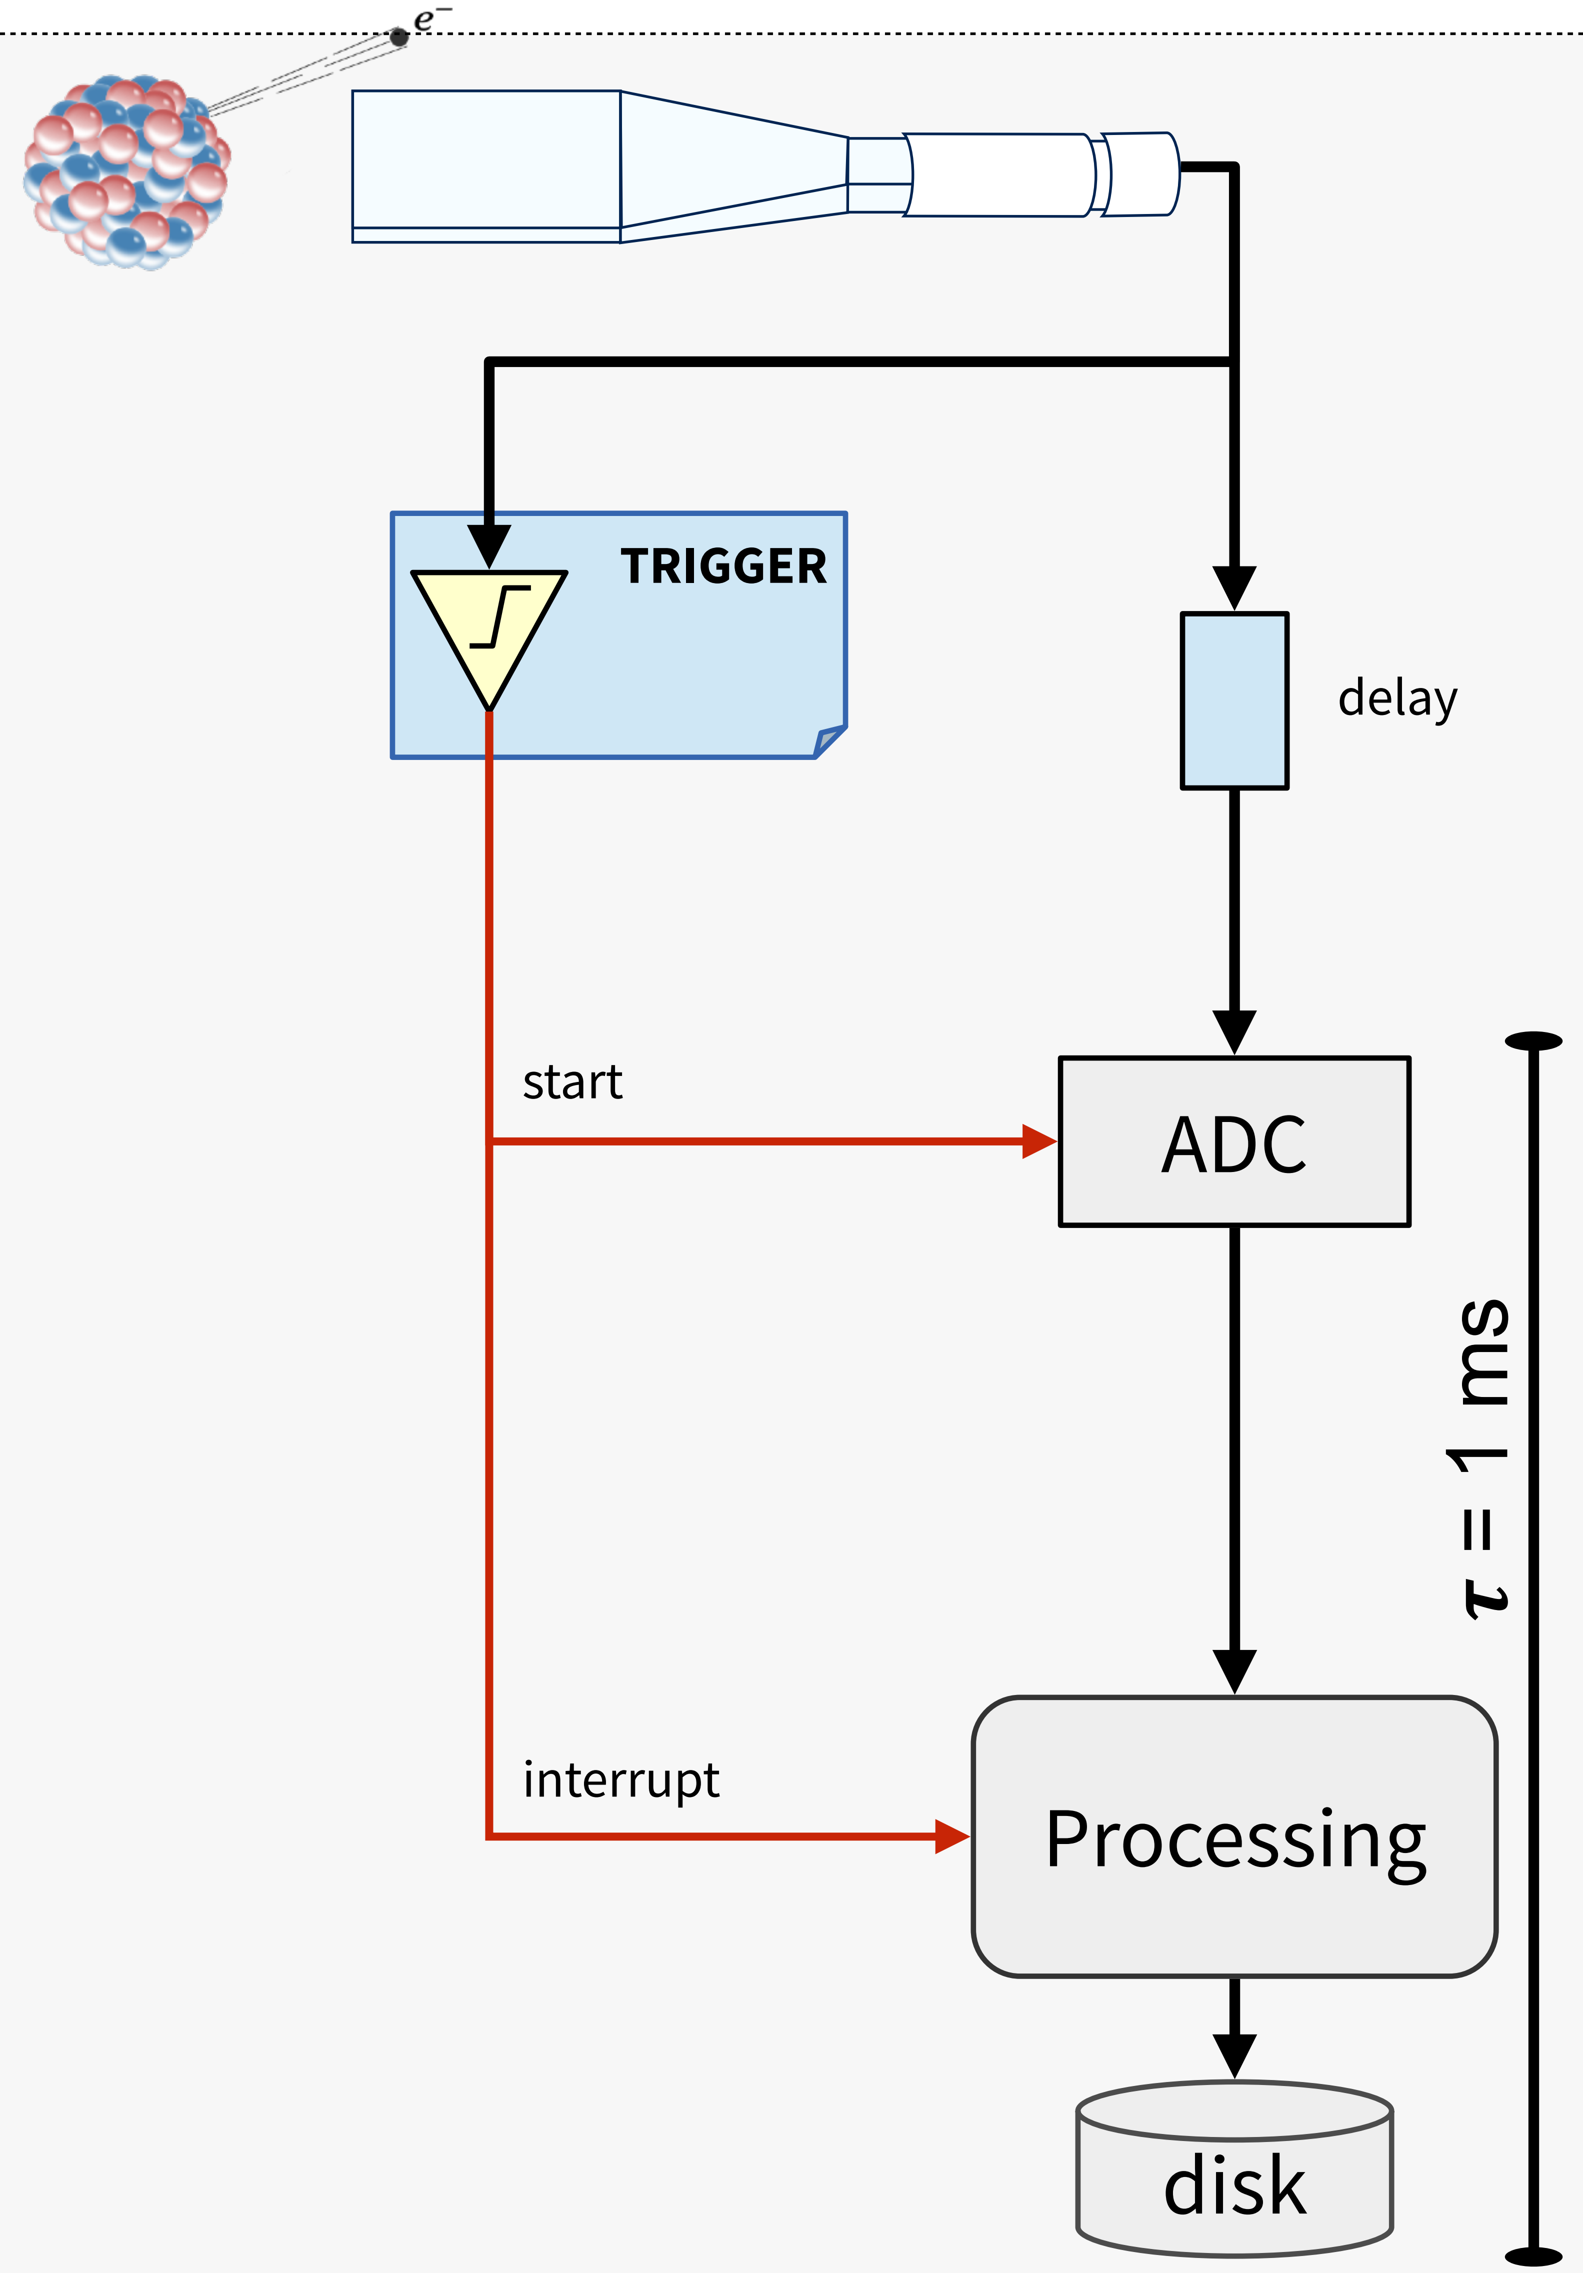
Stochastic process

- Fluctuations in time between events

Let's assume for example

- physics rate f = 1 kHz, i.e. λ = 1 ms
- and, as before, τ = 1 ms

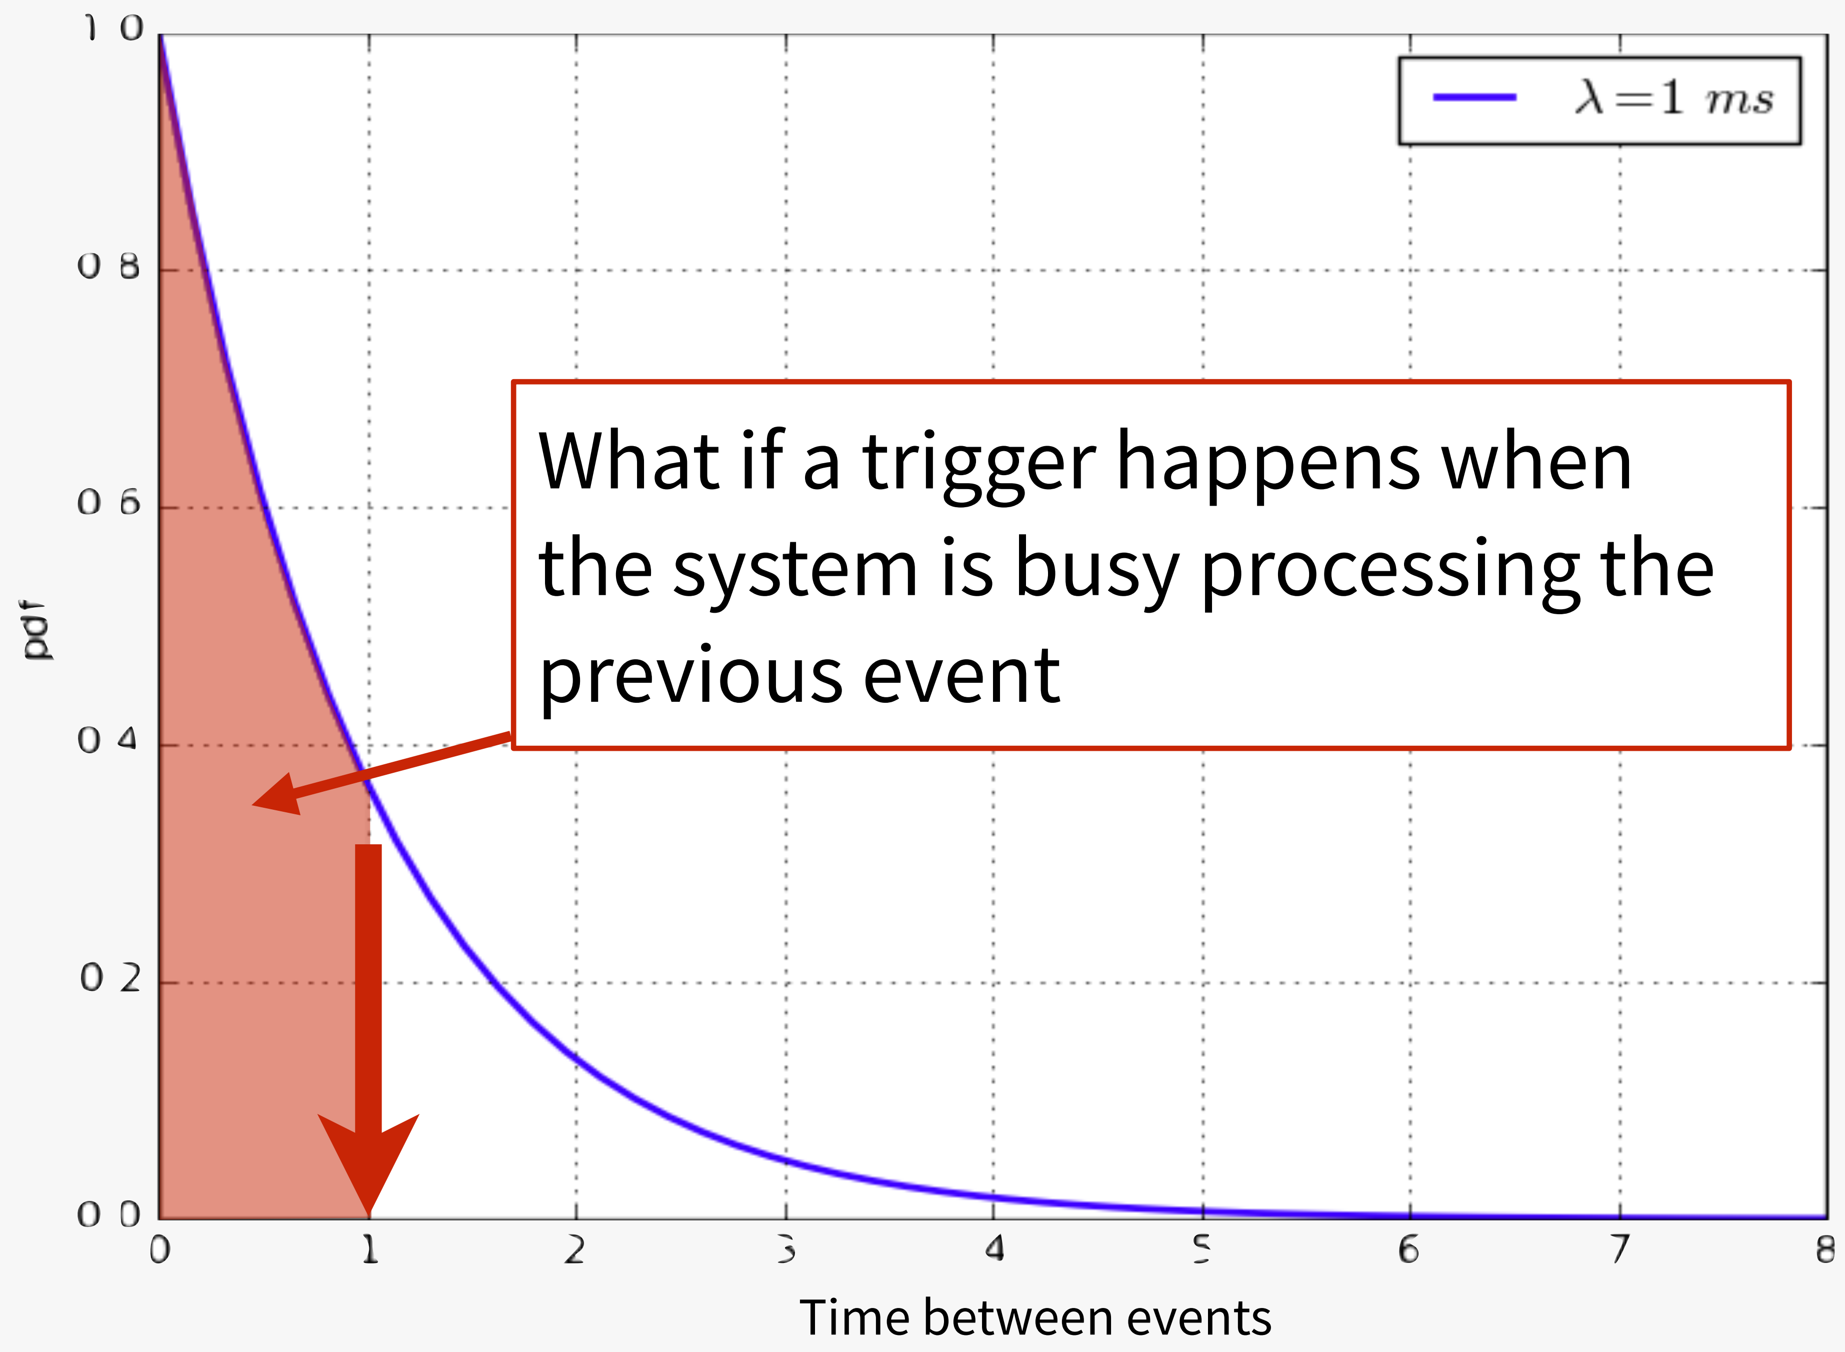


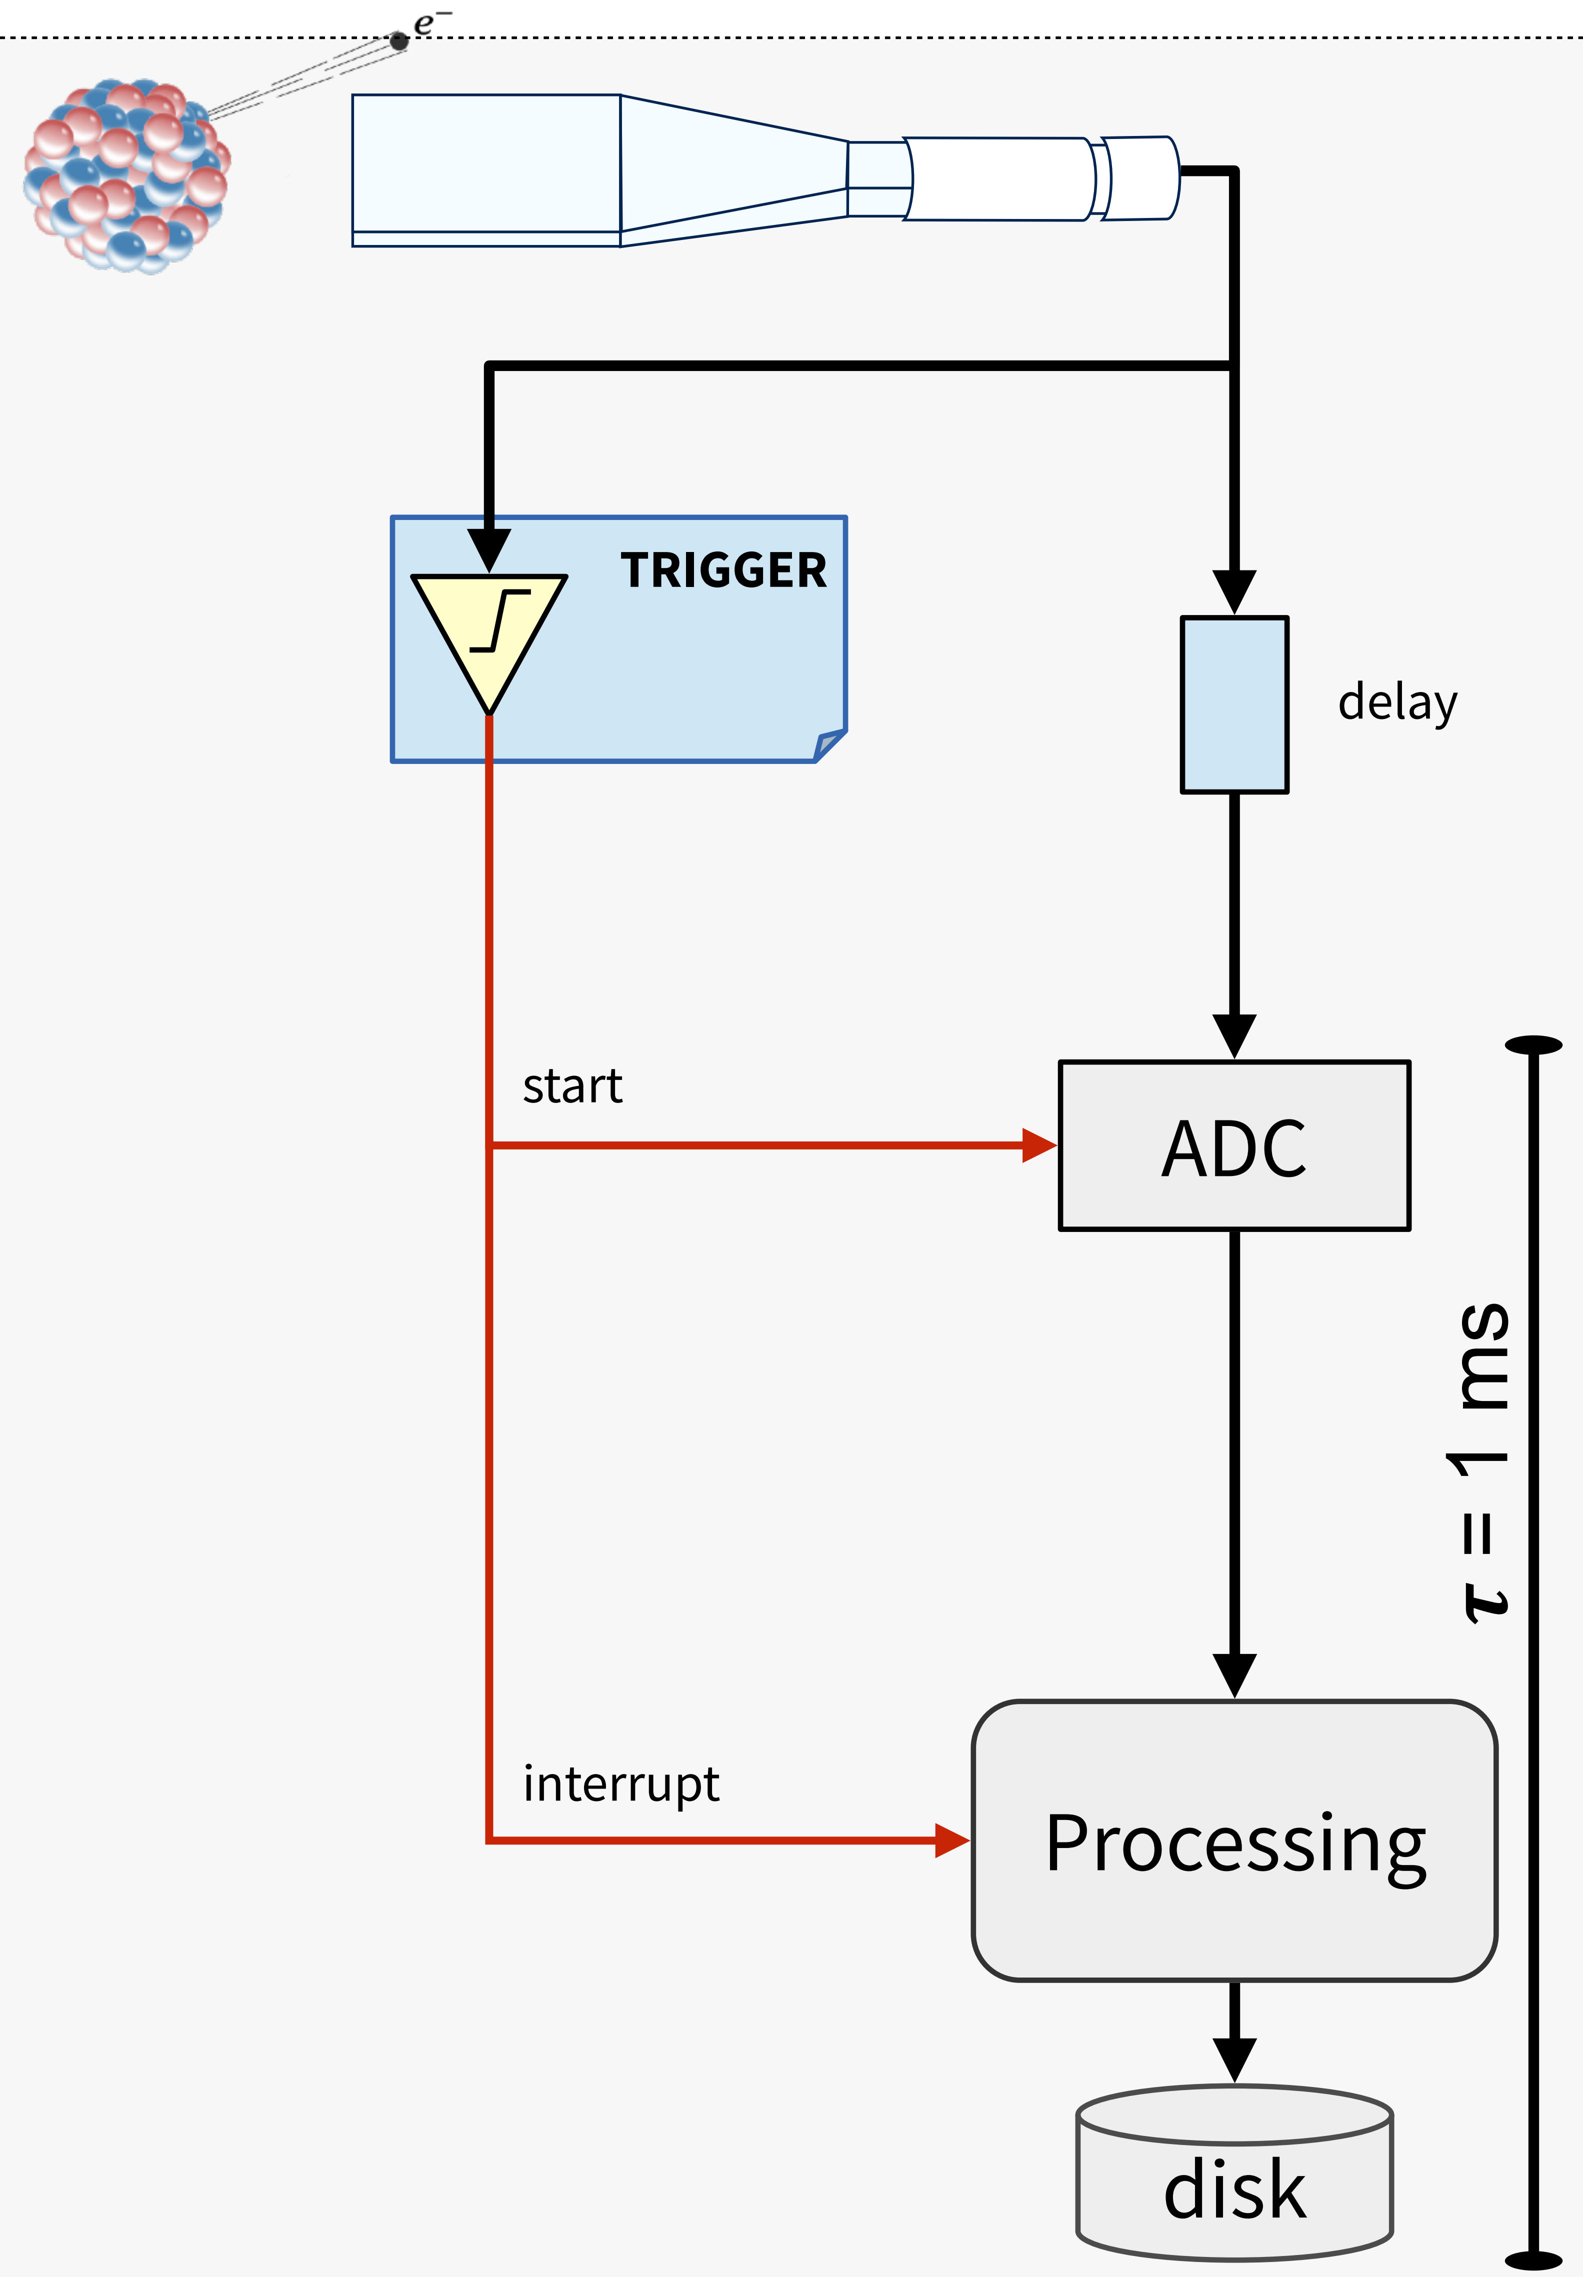


The system is still processing

If a new trigger arrives when the system is still processing the previous event

- The processing of the previous event can be disturbed/corrupted





Thinking…

For stochastic processes, our trigger and daq system needs to be able to:

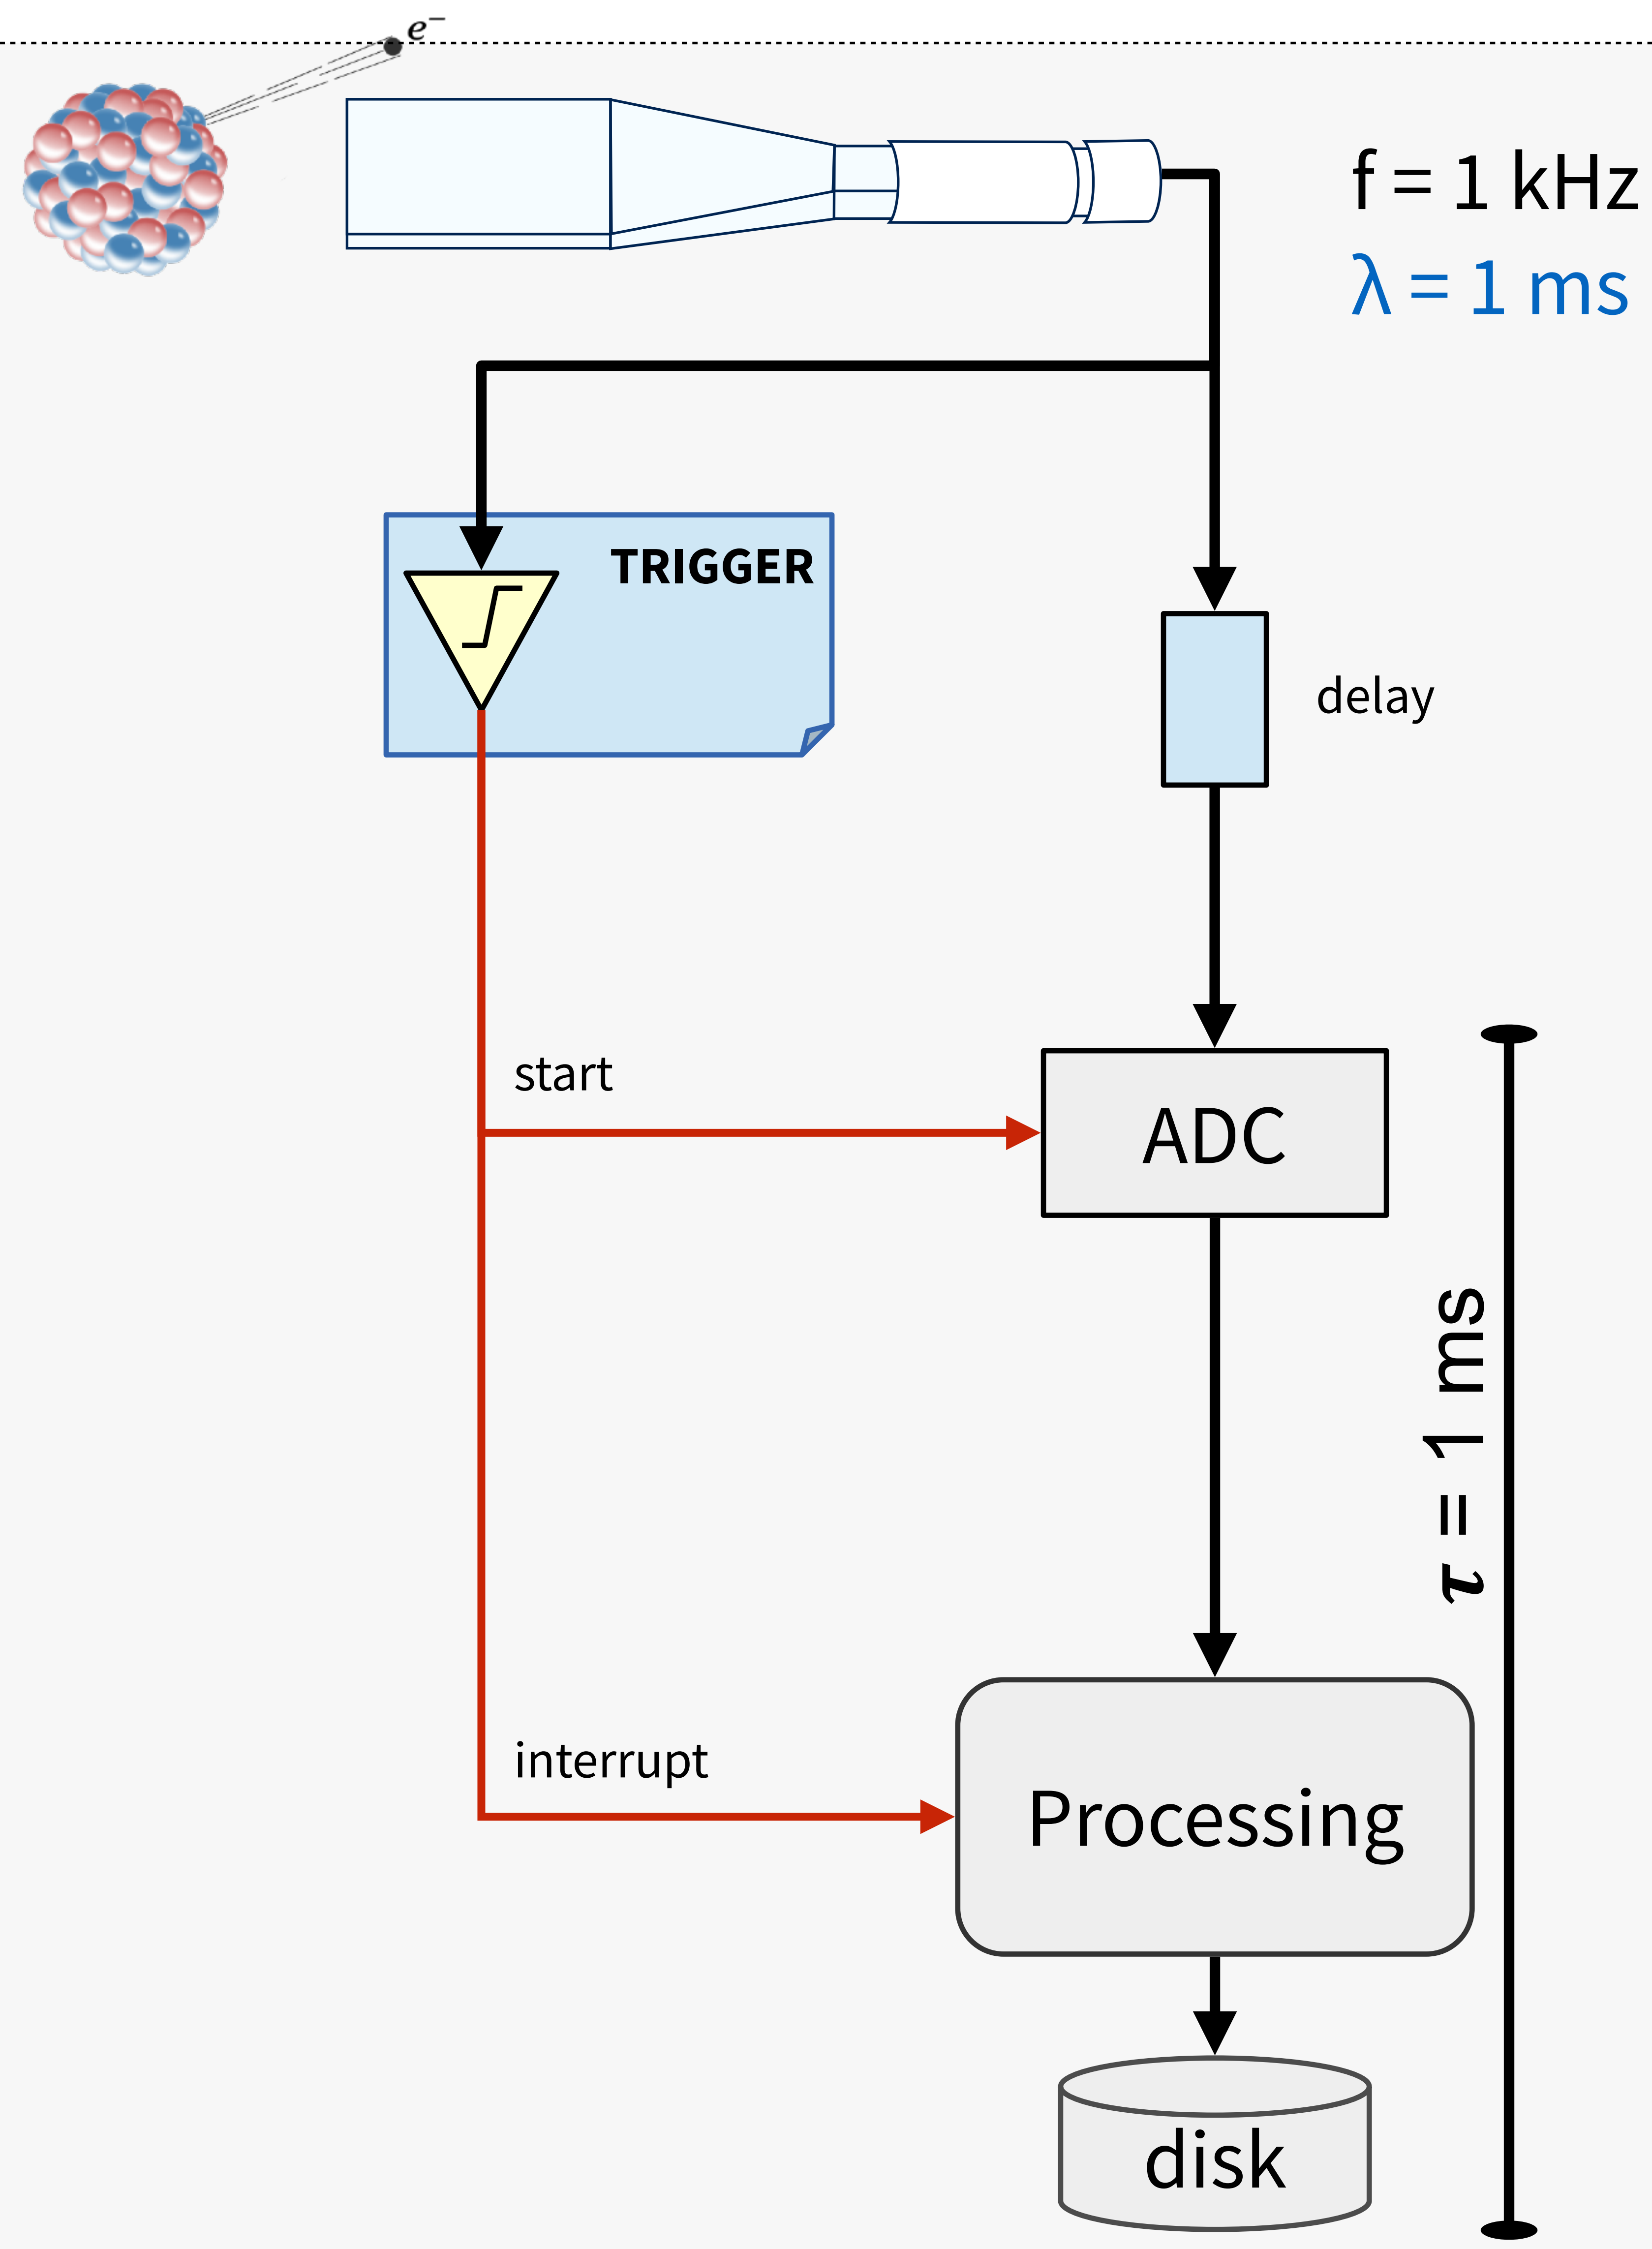
- Determine if there is an “event” (**trigger**)
- Process and store the data from the event (**daq**)
- Have a feedback mechanism,
  to know if the data processing pipeline
  is free to process a new event:
  busy logic

Busy logic

The **busy logic** avoids triggers while the system is busy in processing

A minimal **busy logic** can be implemented with

- an **AND** gate
- a **NOT** gate
- a **flip-flop**
  - bistable circuit that changes state (Q) by signals applied to the control inputs (SET, CLEAR)

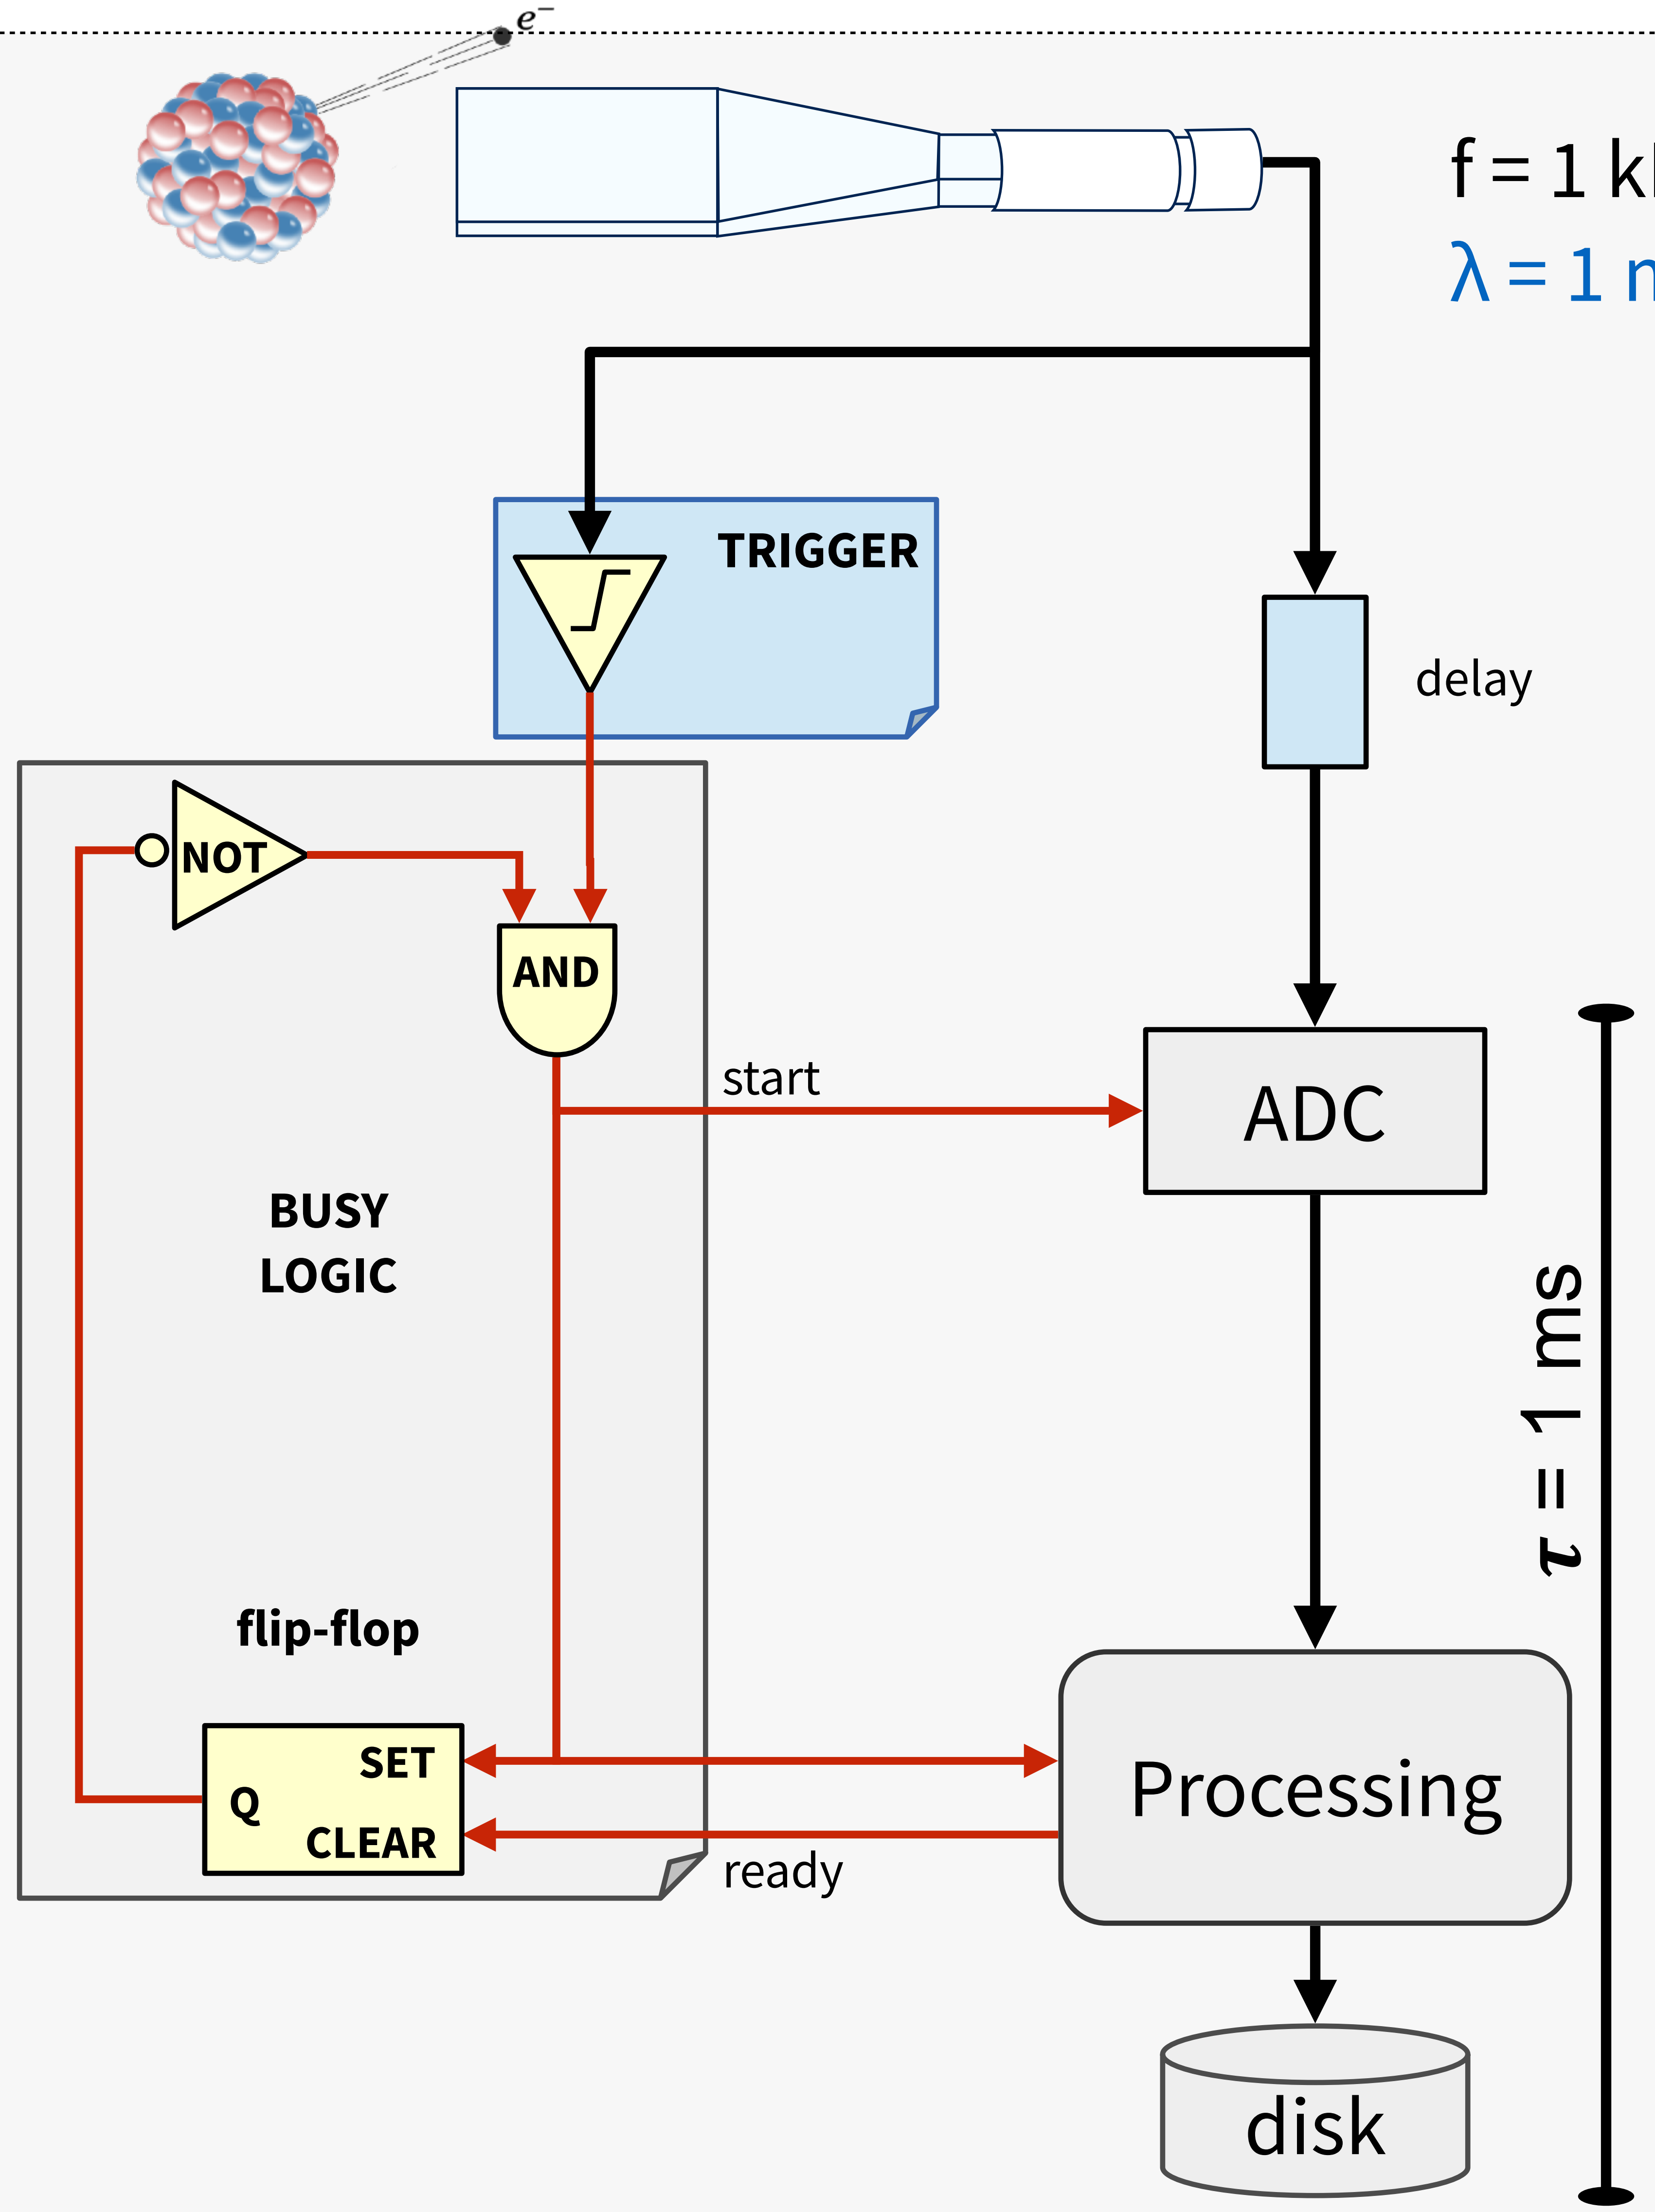


Busy logic

The **busy logic** avoids triggers while the system is busy in processing

A minimal **busy logic** can be implemented with

- an **AND** gate
- a **NOT** gate
- a **flip-flop**
  - bistable circuit that changes state (Q) by signals applied to the control inputs (SET, CLEAR)

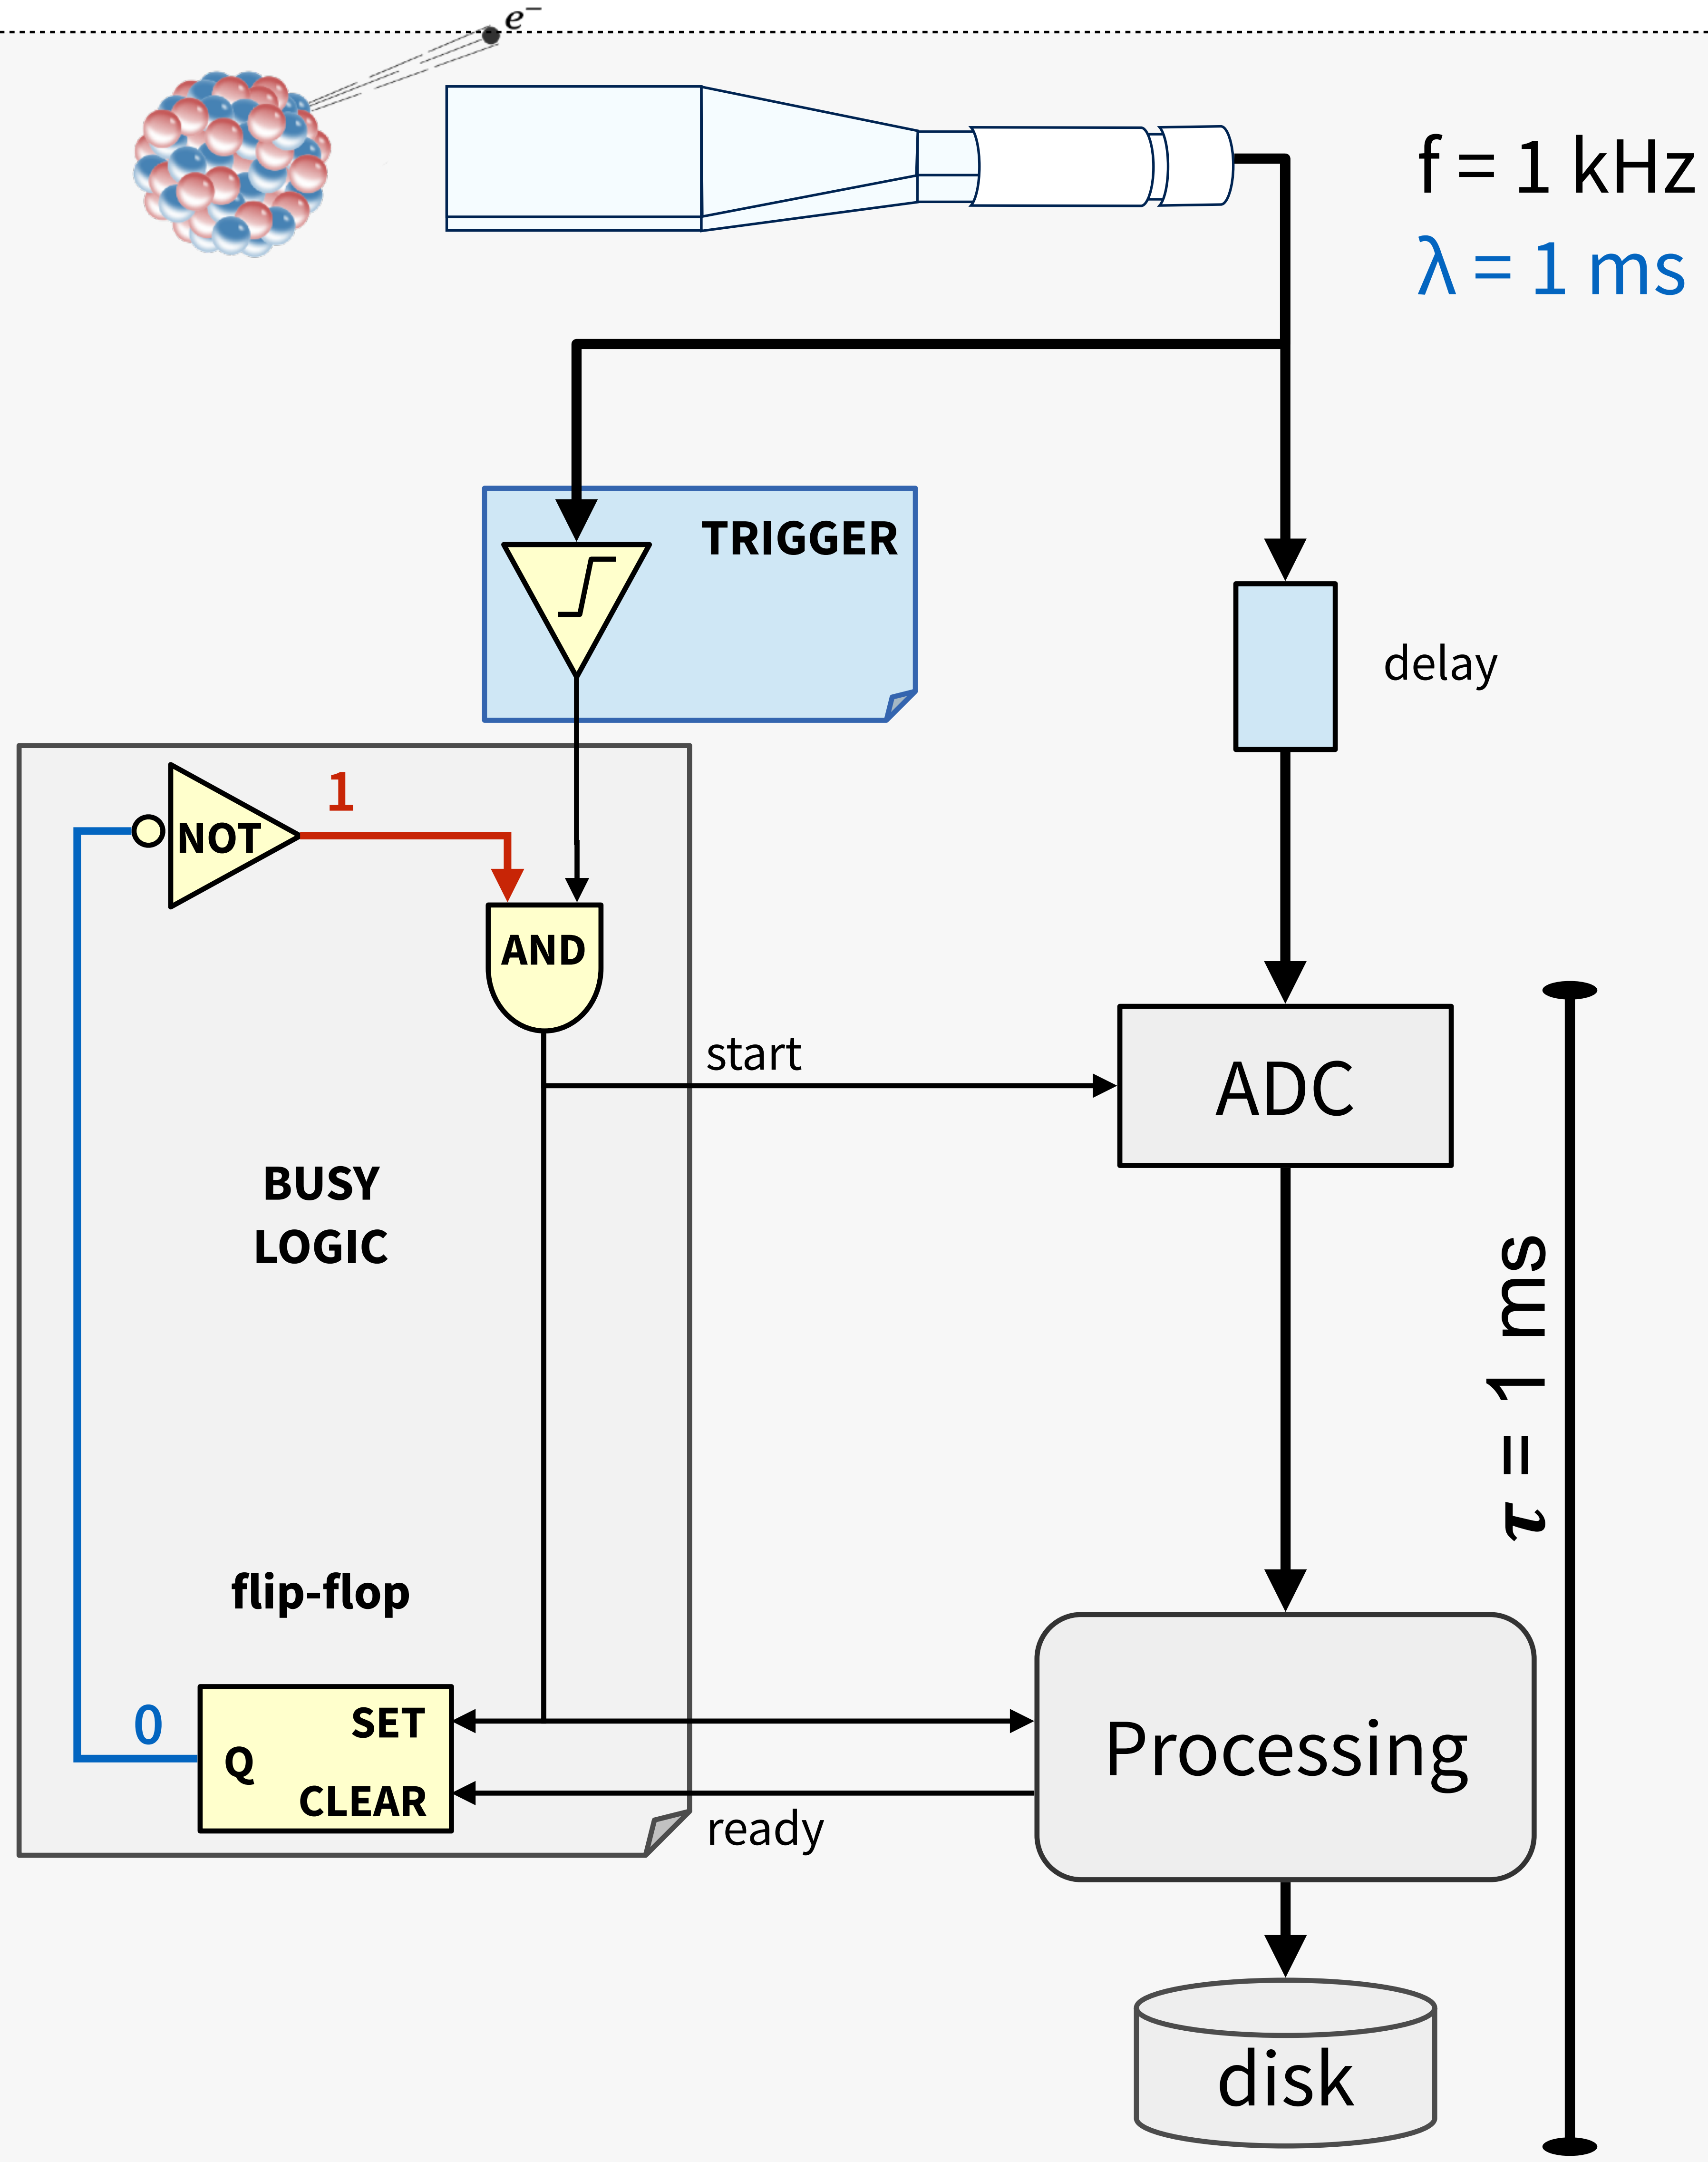


Busy logic

Start of run

- the flip-flop output is down (ground state)
- via the NOT, one of the port of the AND gate is set to up (opened)

i.e. **system ready for new triggers**

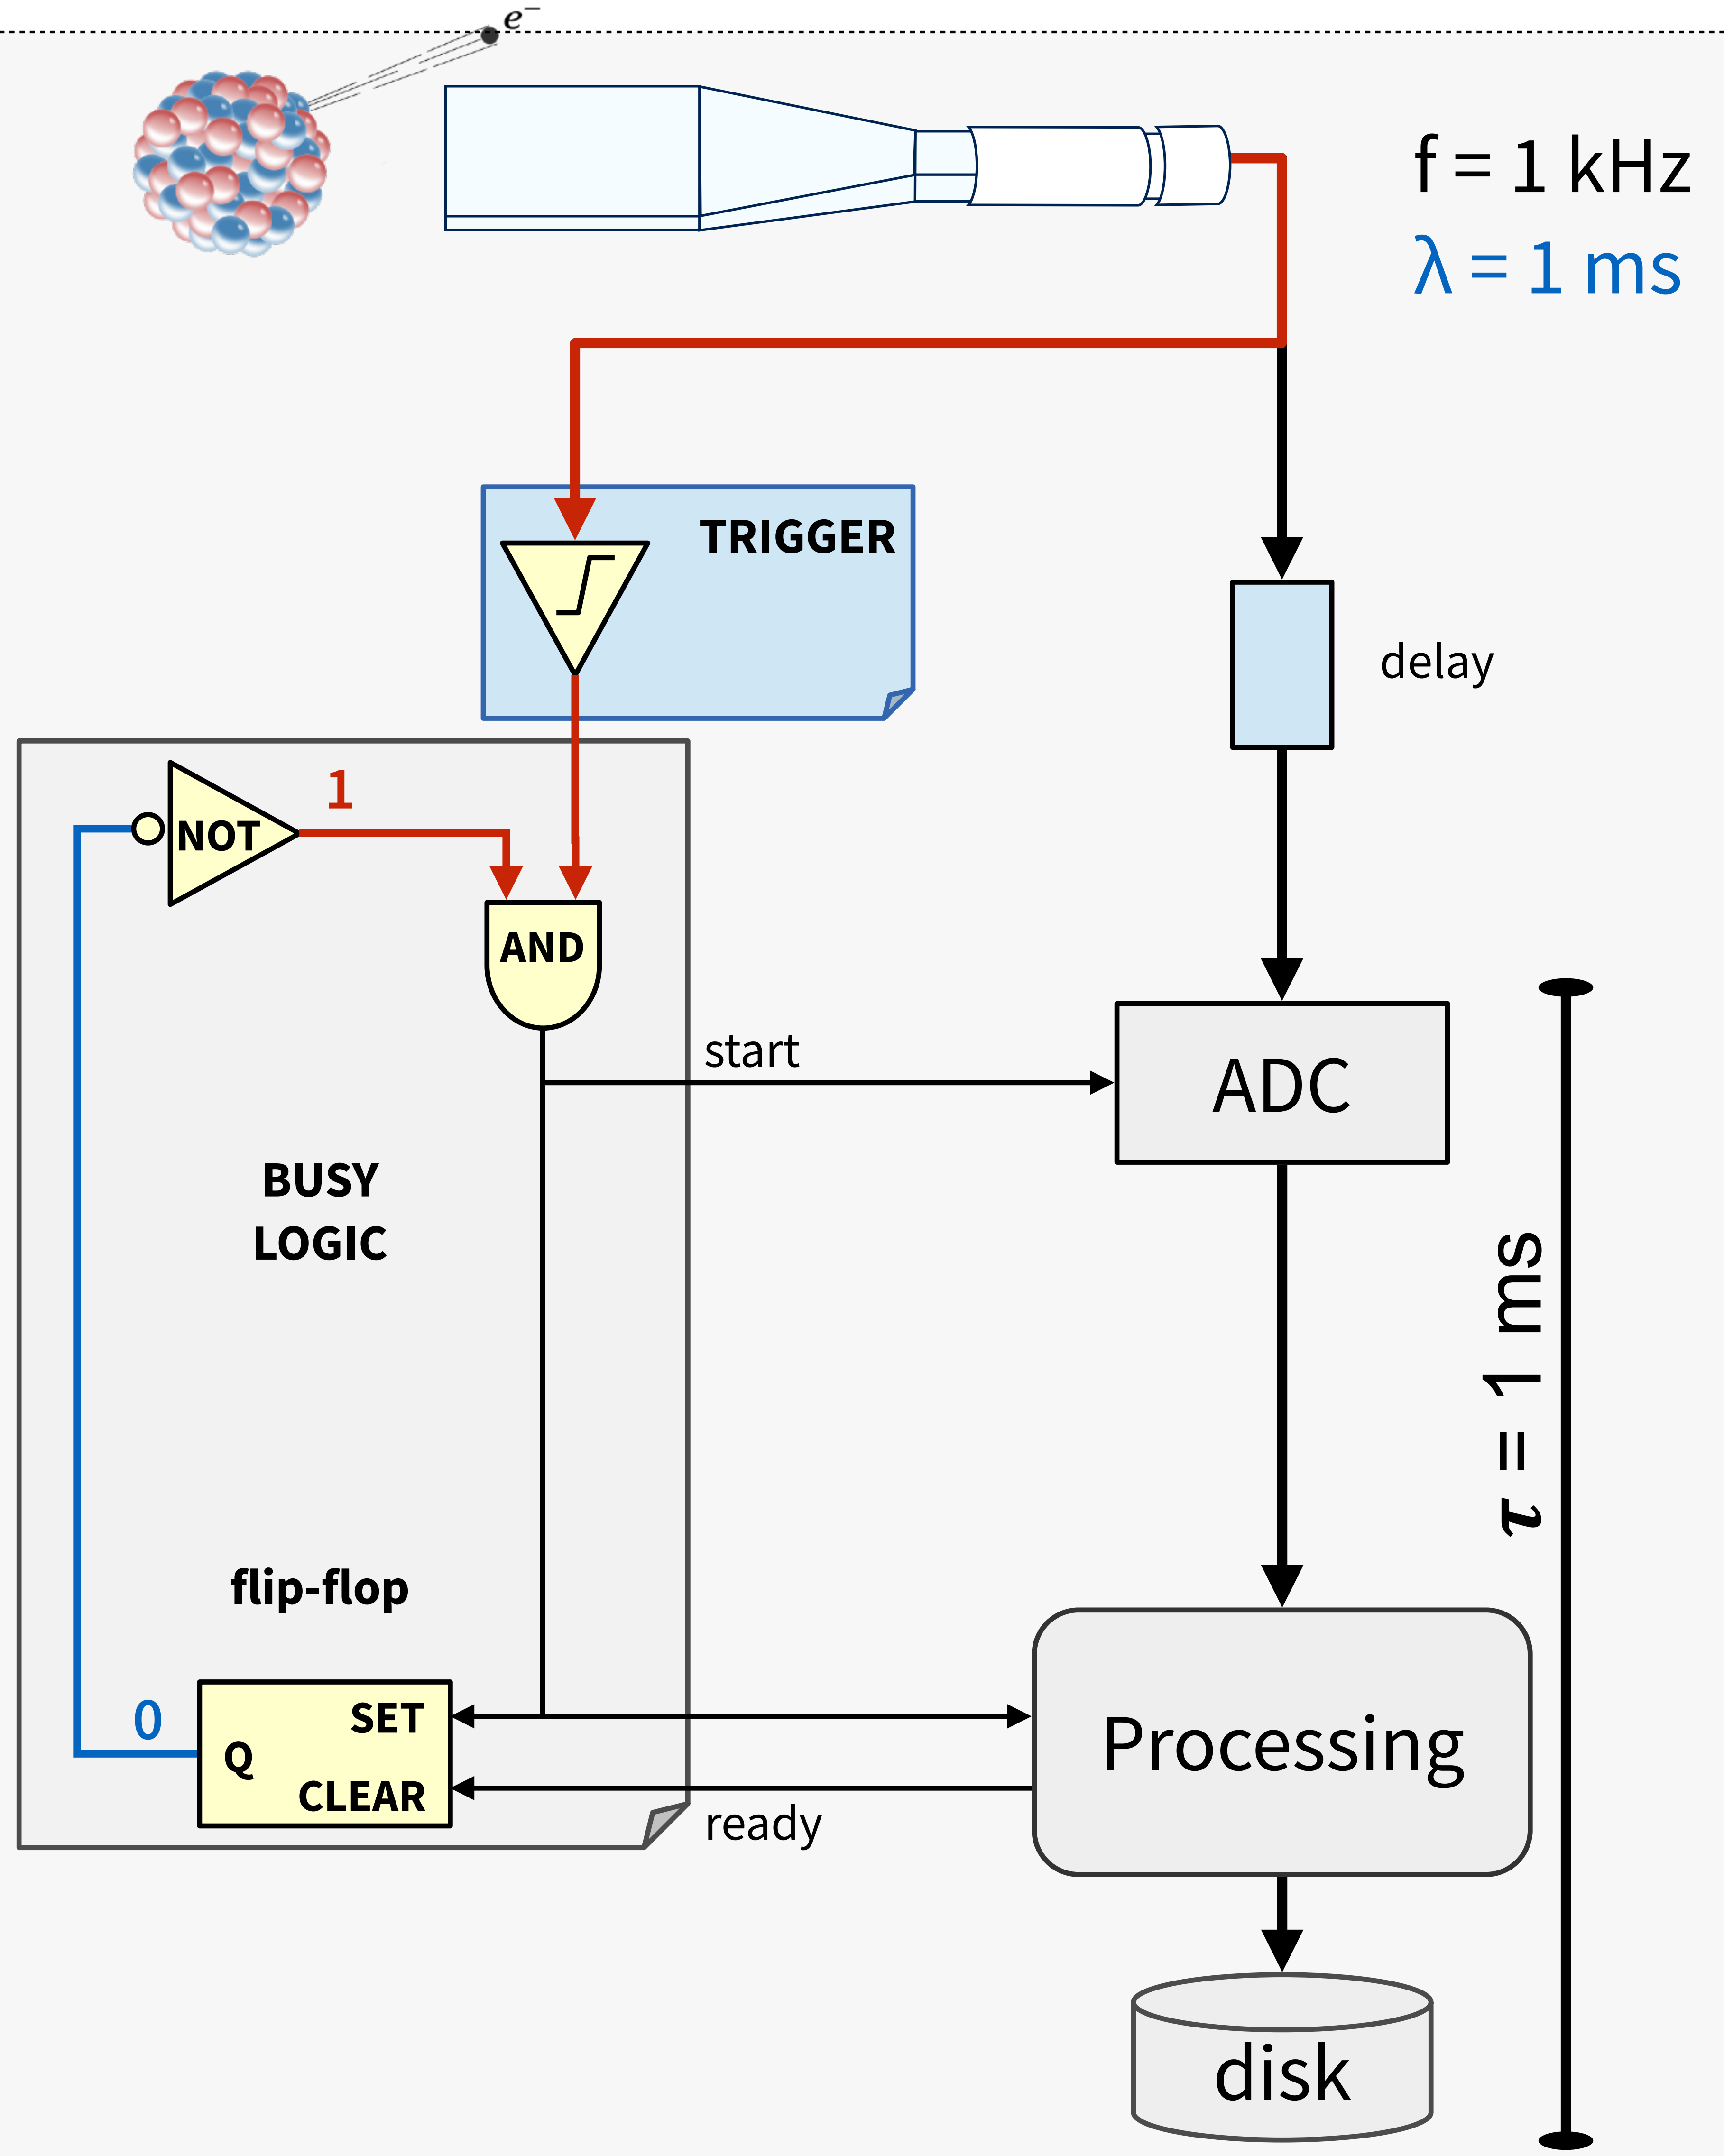


Busy logic

If a trigger arrives, the signal finds the AND gate open, so:

- The ADC is started
- The processing is started
- The flip-flop is flipped
- One of the AND inputs is now steadily down (closed)

Any new trigger is inhibited by the AND gate (busy)

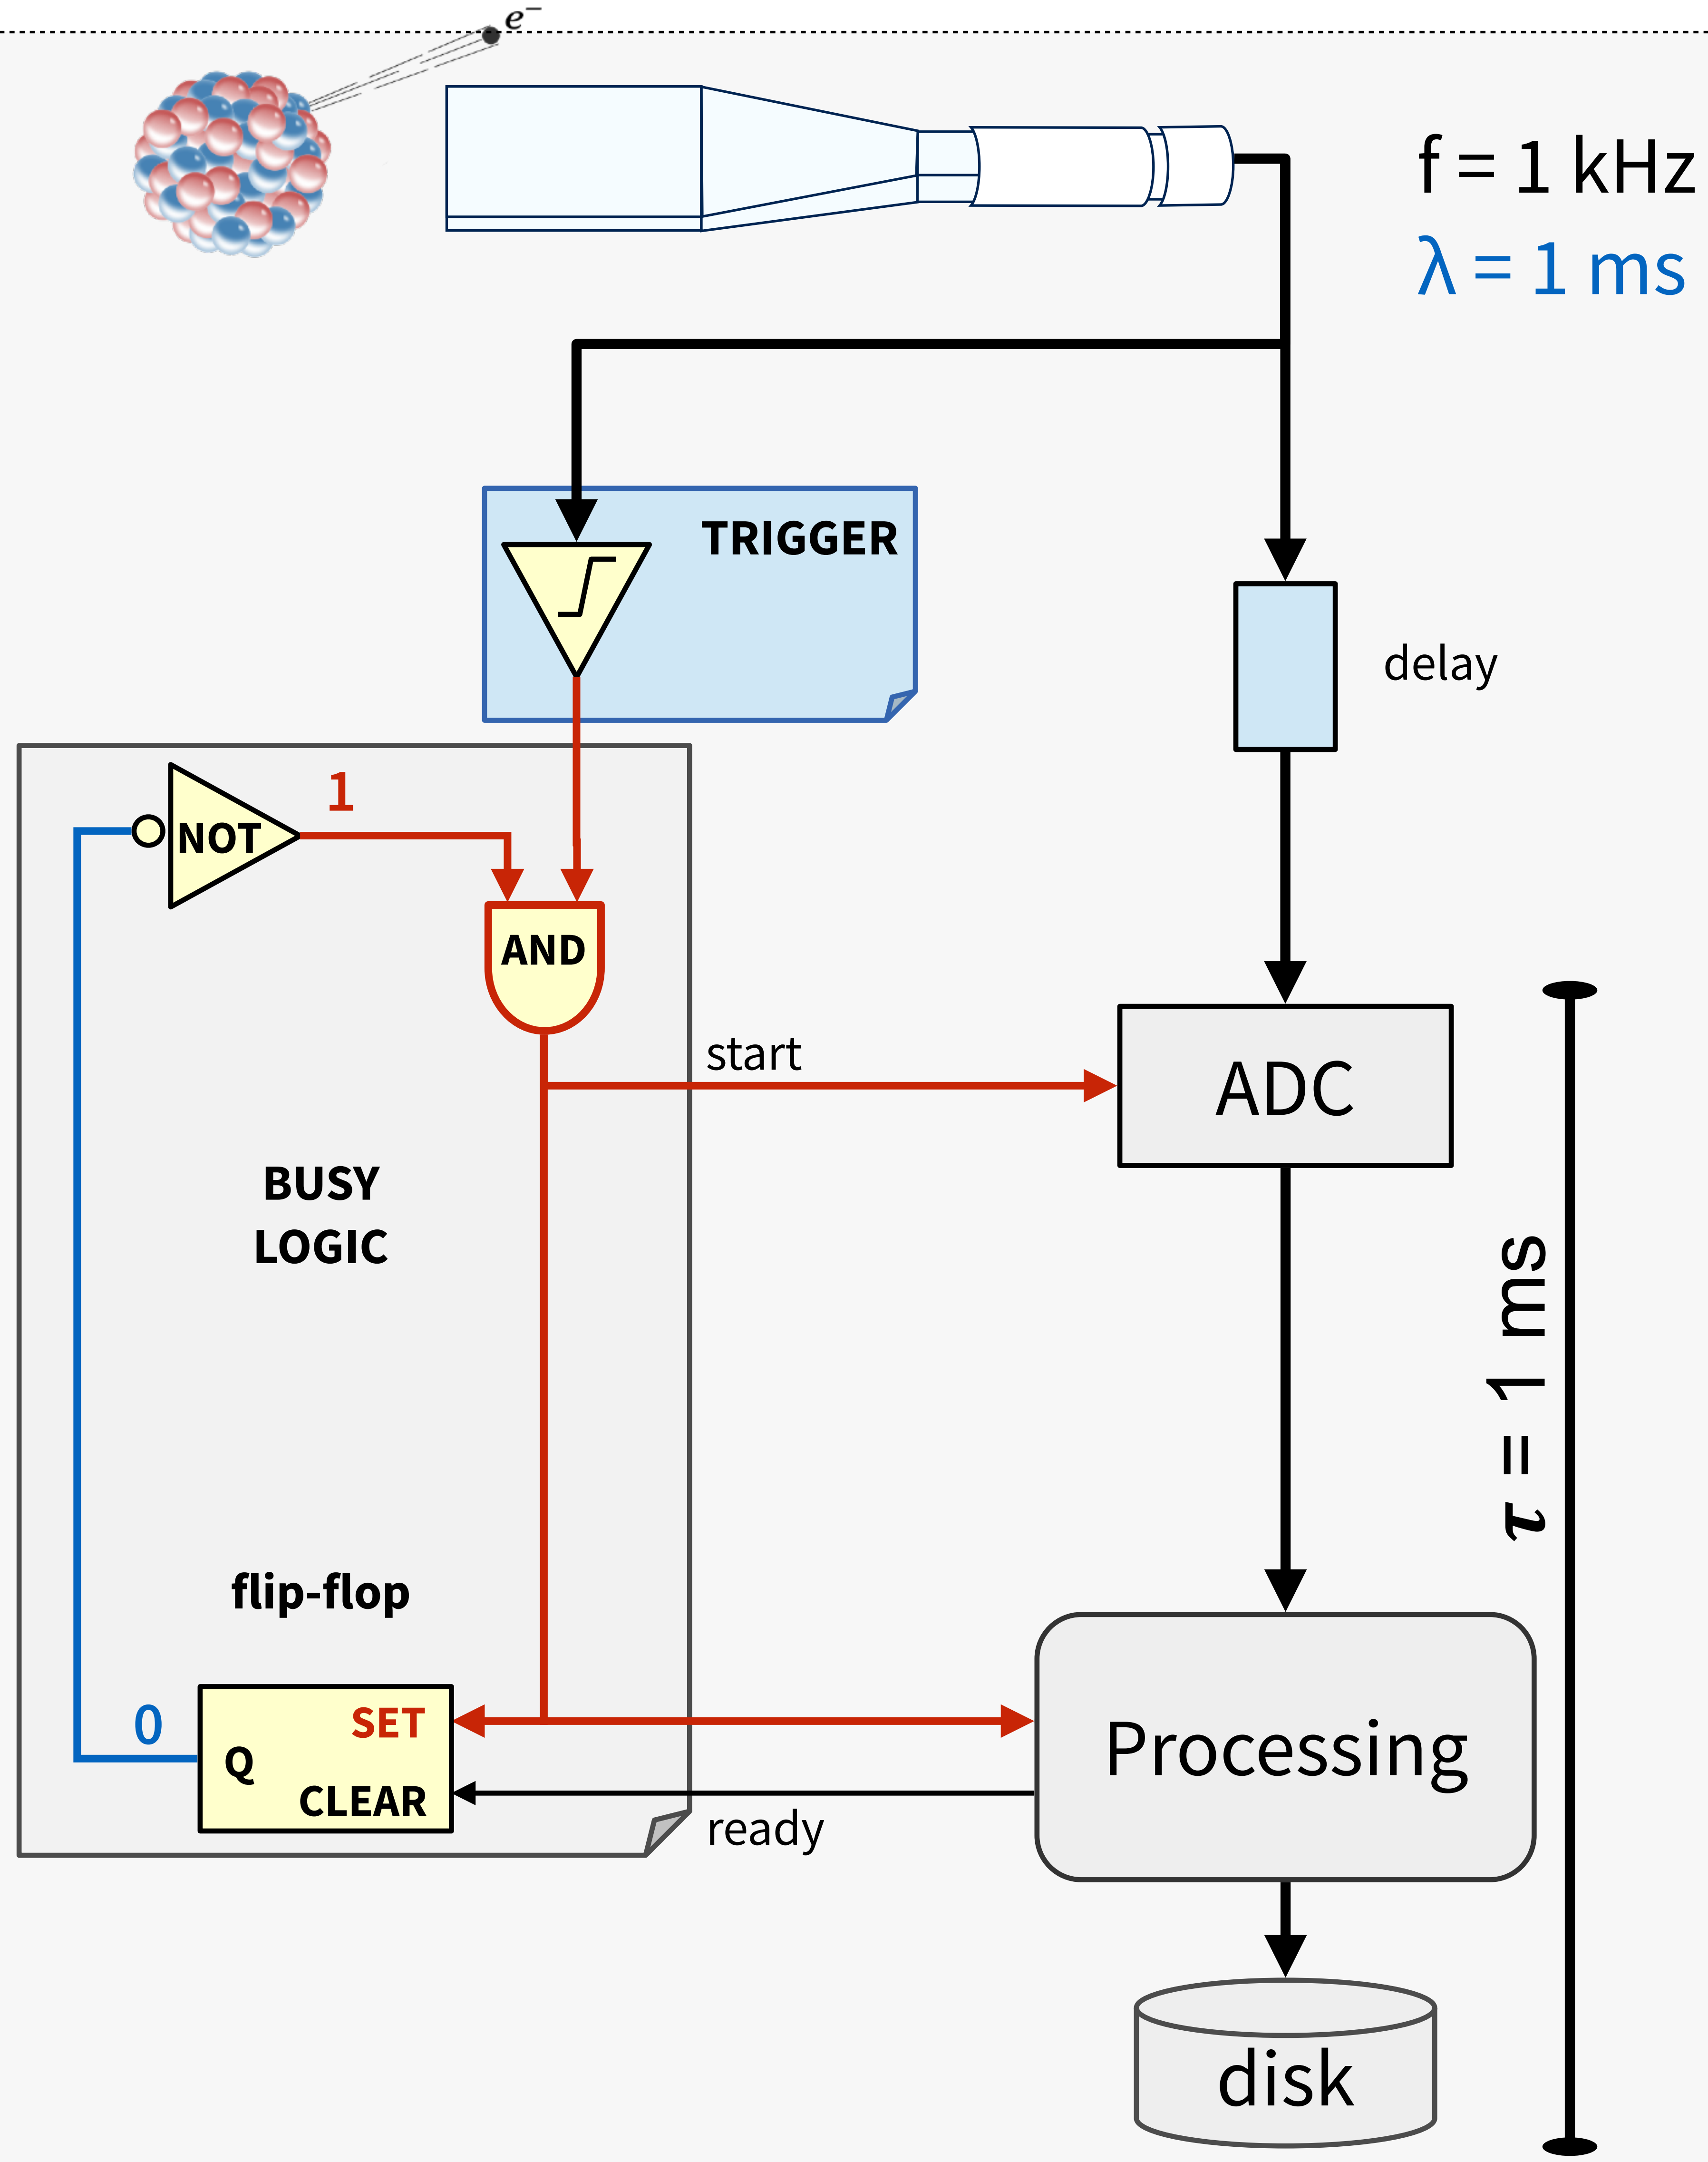


Busy logic

If a trigger arrives, the signal finds the AND gate open, so:

- The ADC is started
- The processing is started
- The flip-flop is flipped
- One of the AND inputs is now steadily down (closed)

Any new trigger is inhibited by the AND gate (busy)

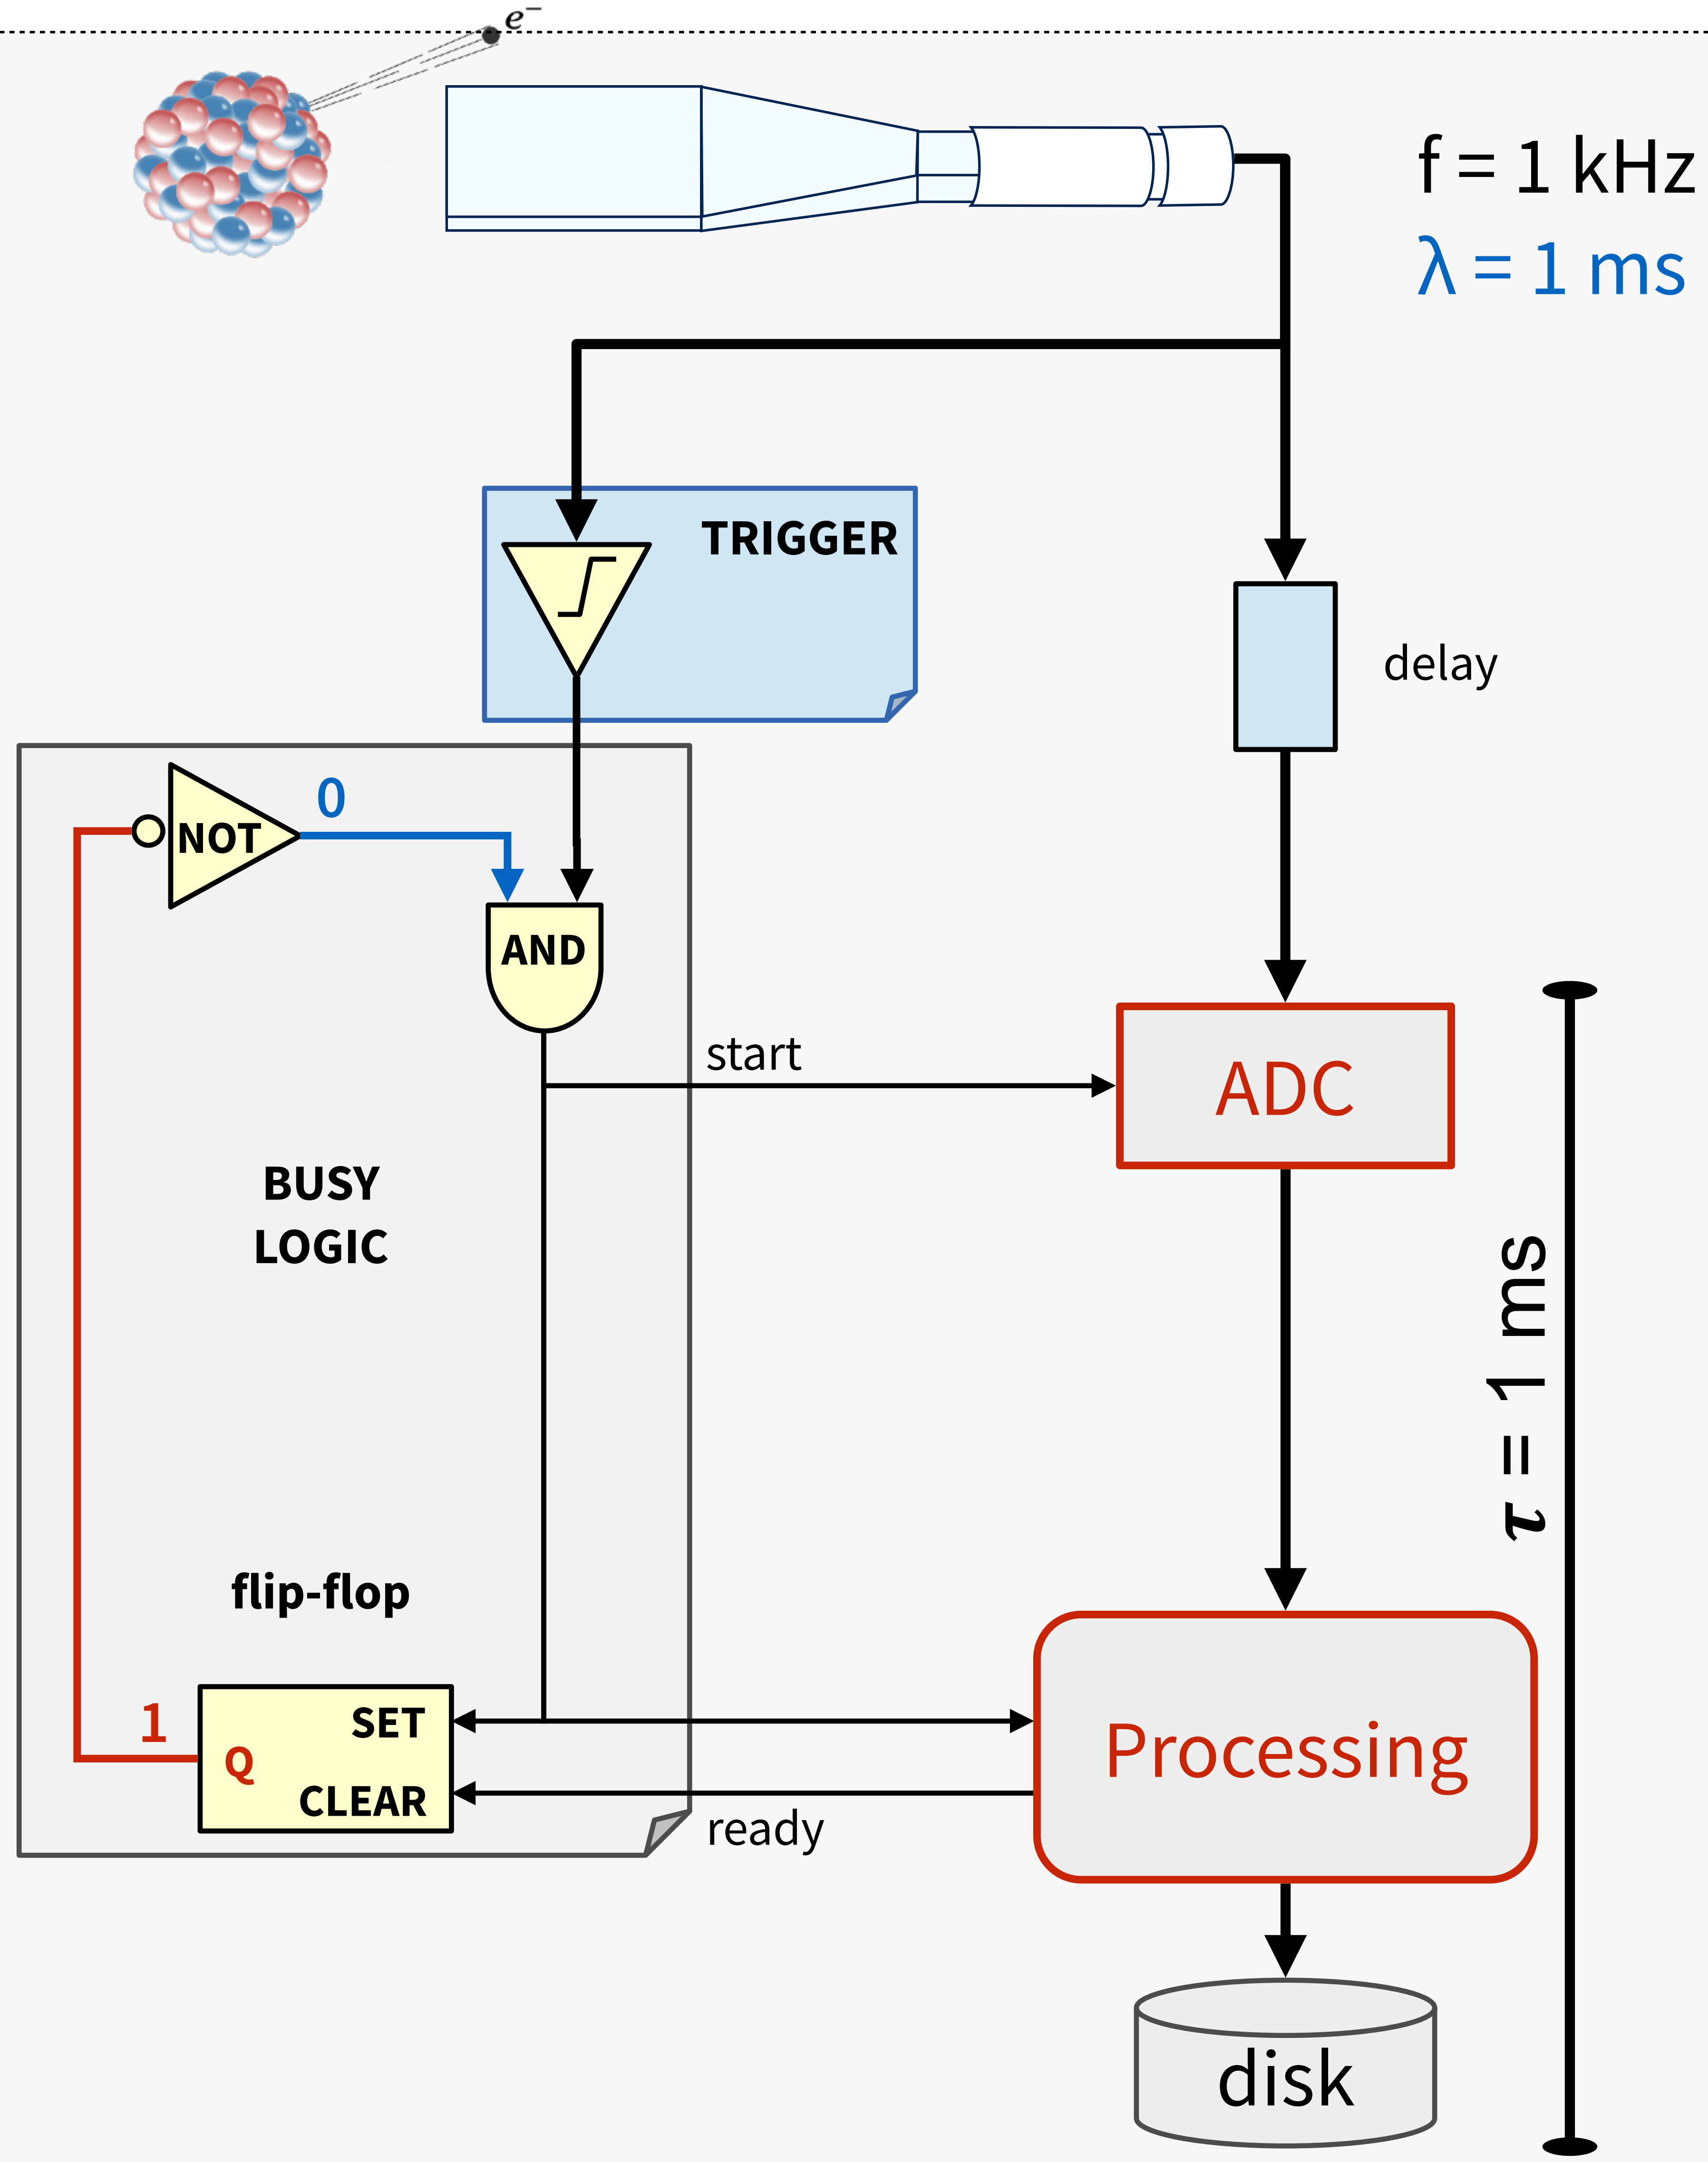


Busy logic

If a trigger arrives, the signal finds the AND gate open, so:

- The ADC is started
- The processing is started
- The flip-flop is flipped
- One of the AND inputs is now steadily down (closed)

Any new trigger is inhibited by the AND gate (busy)

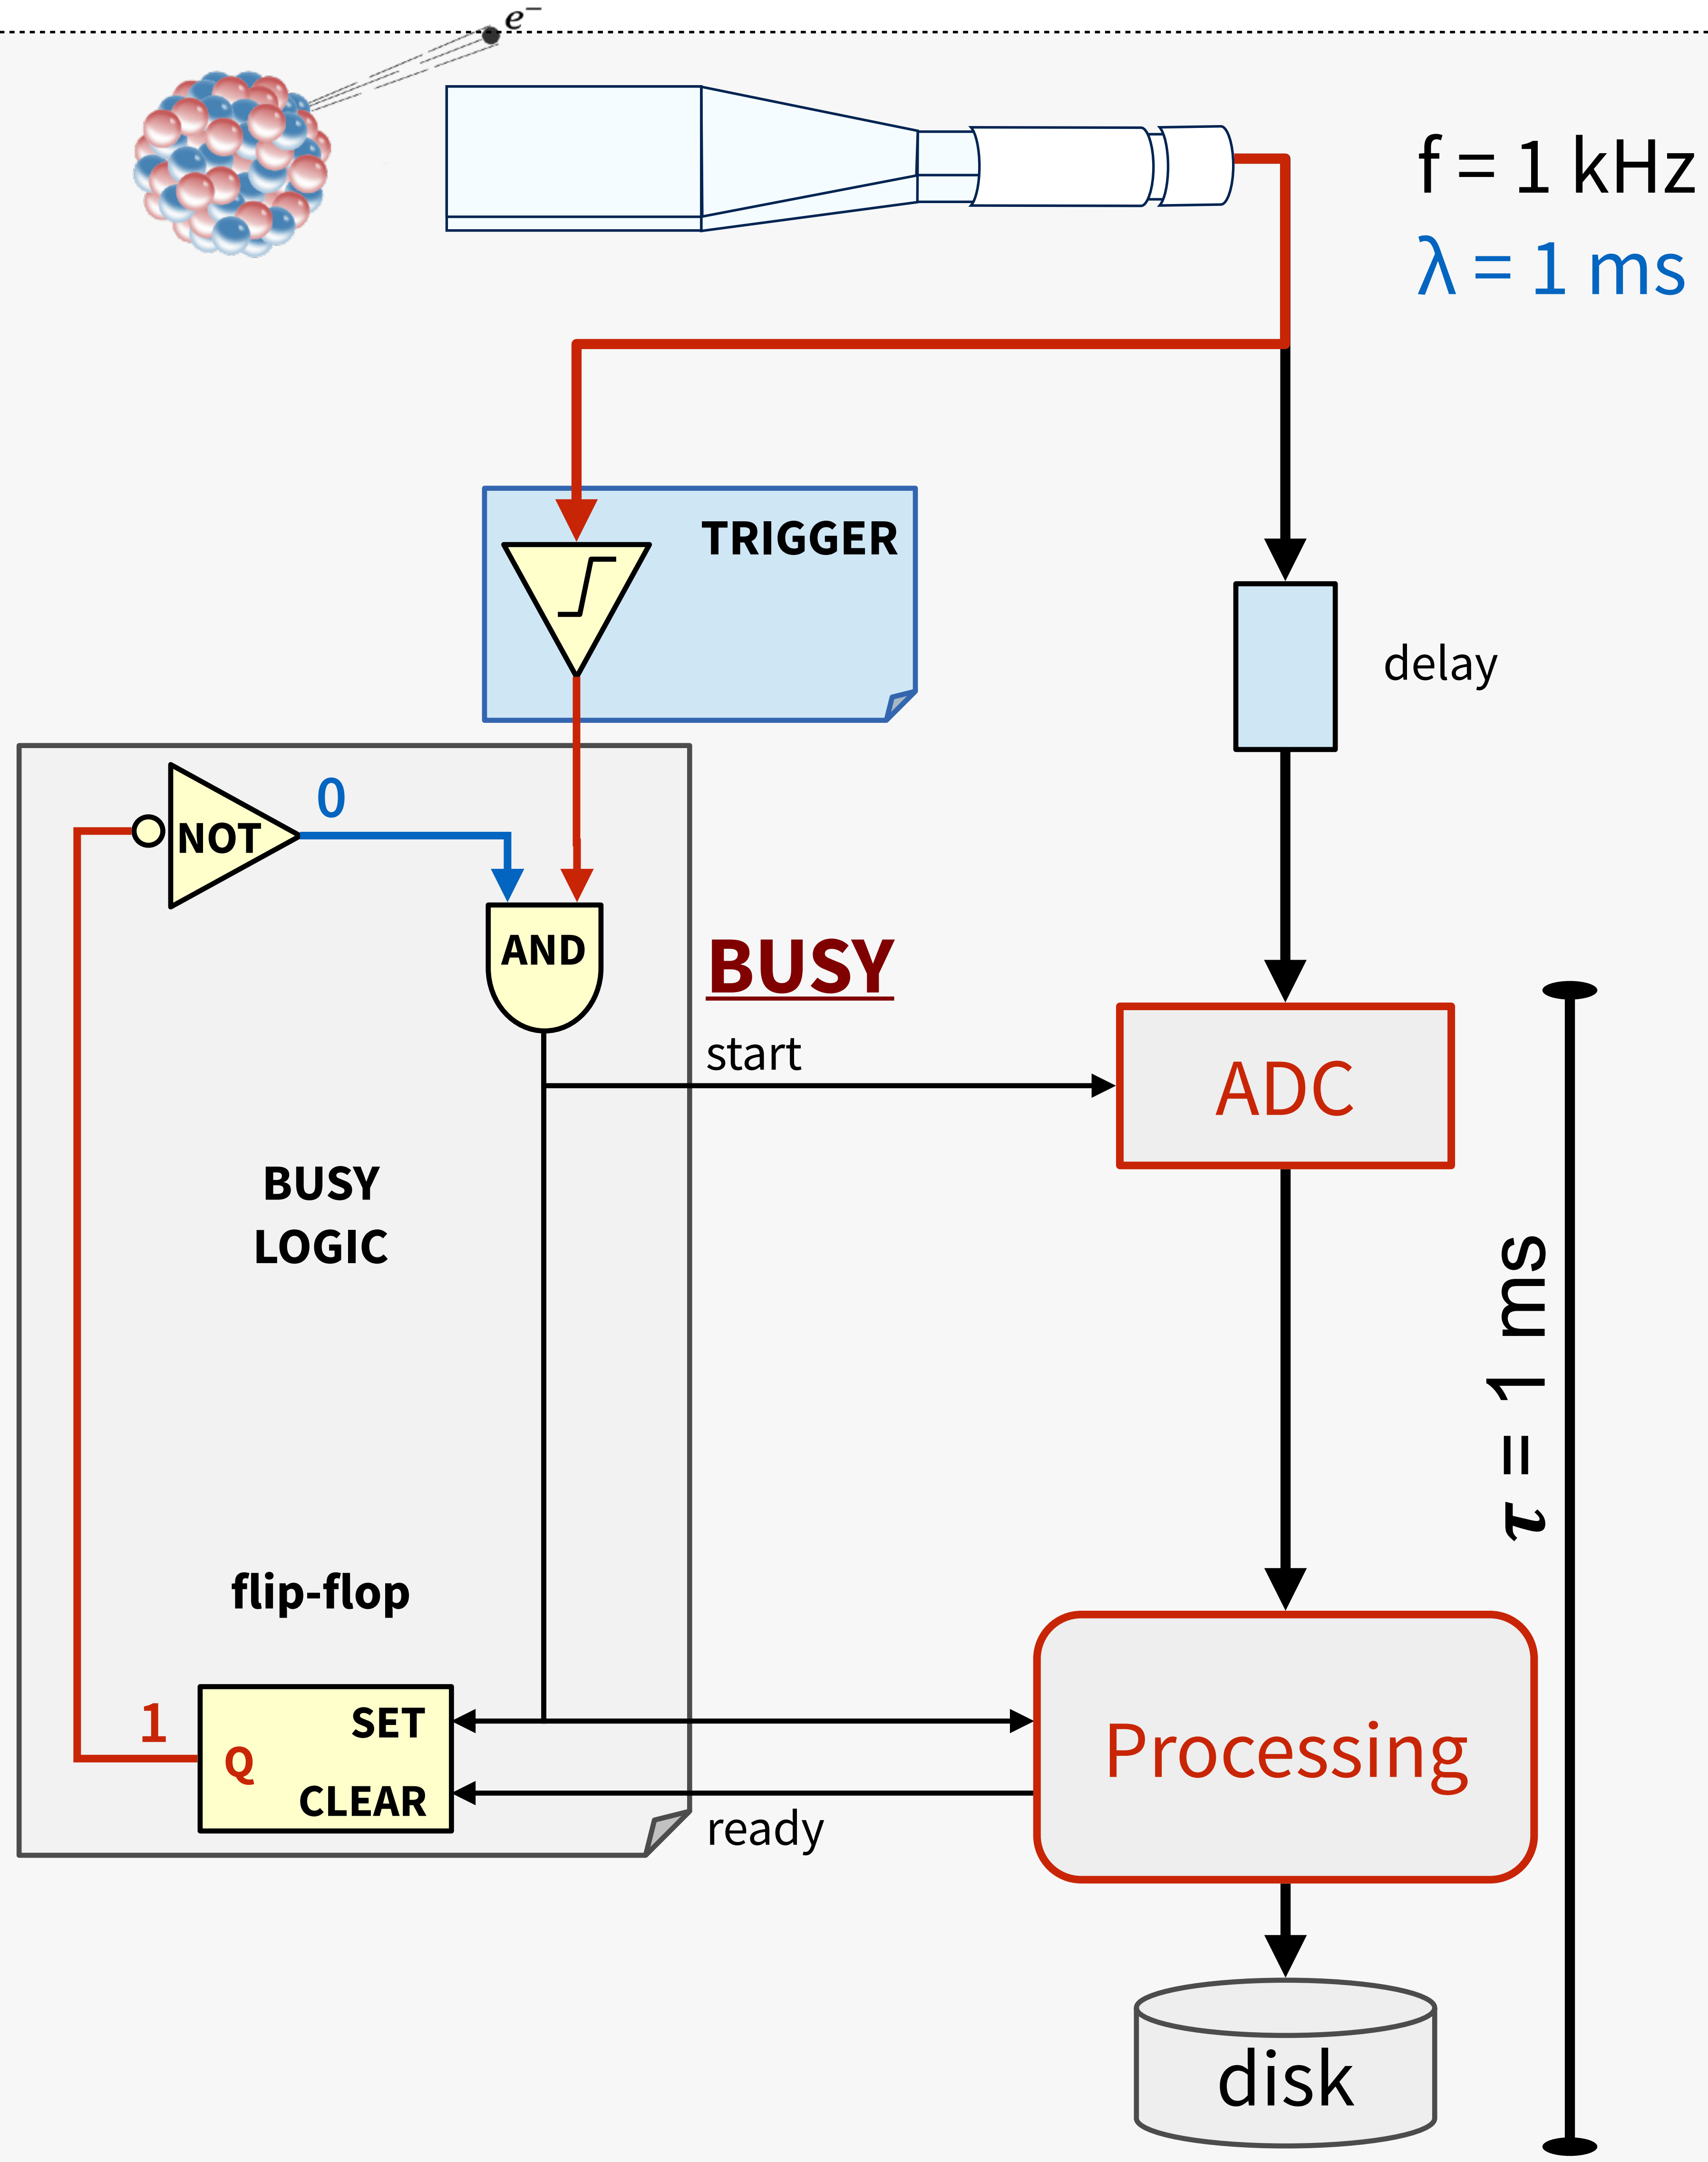


Busy logic

If a trigger arrives, the signal finds the AND gate open, so:

- The ADC is started
- The processing is started
- The flip-flop is flipped
- One of the AND inputs is now steadily down (closed)

Any new trigger is inhibited by the AND gate (busy)



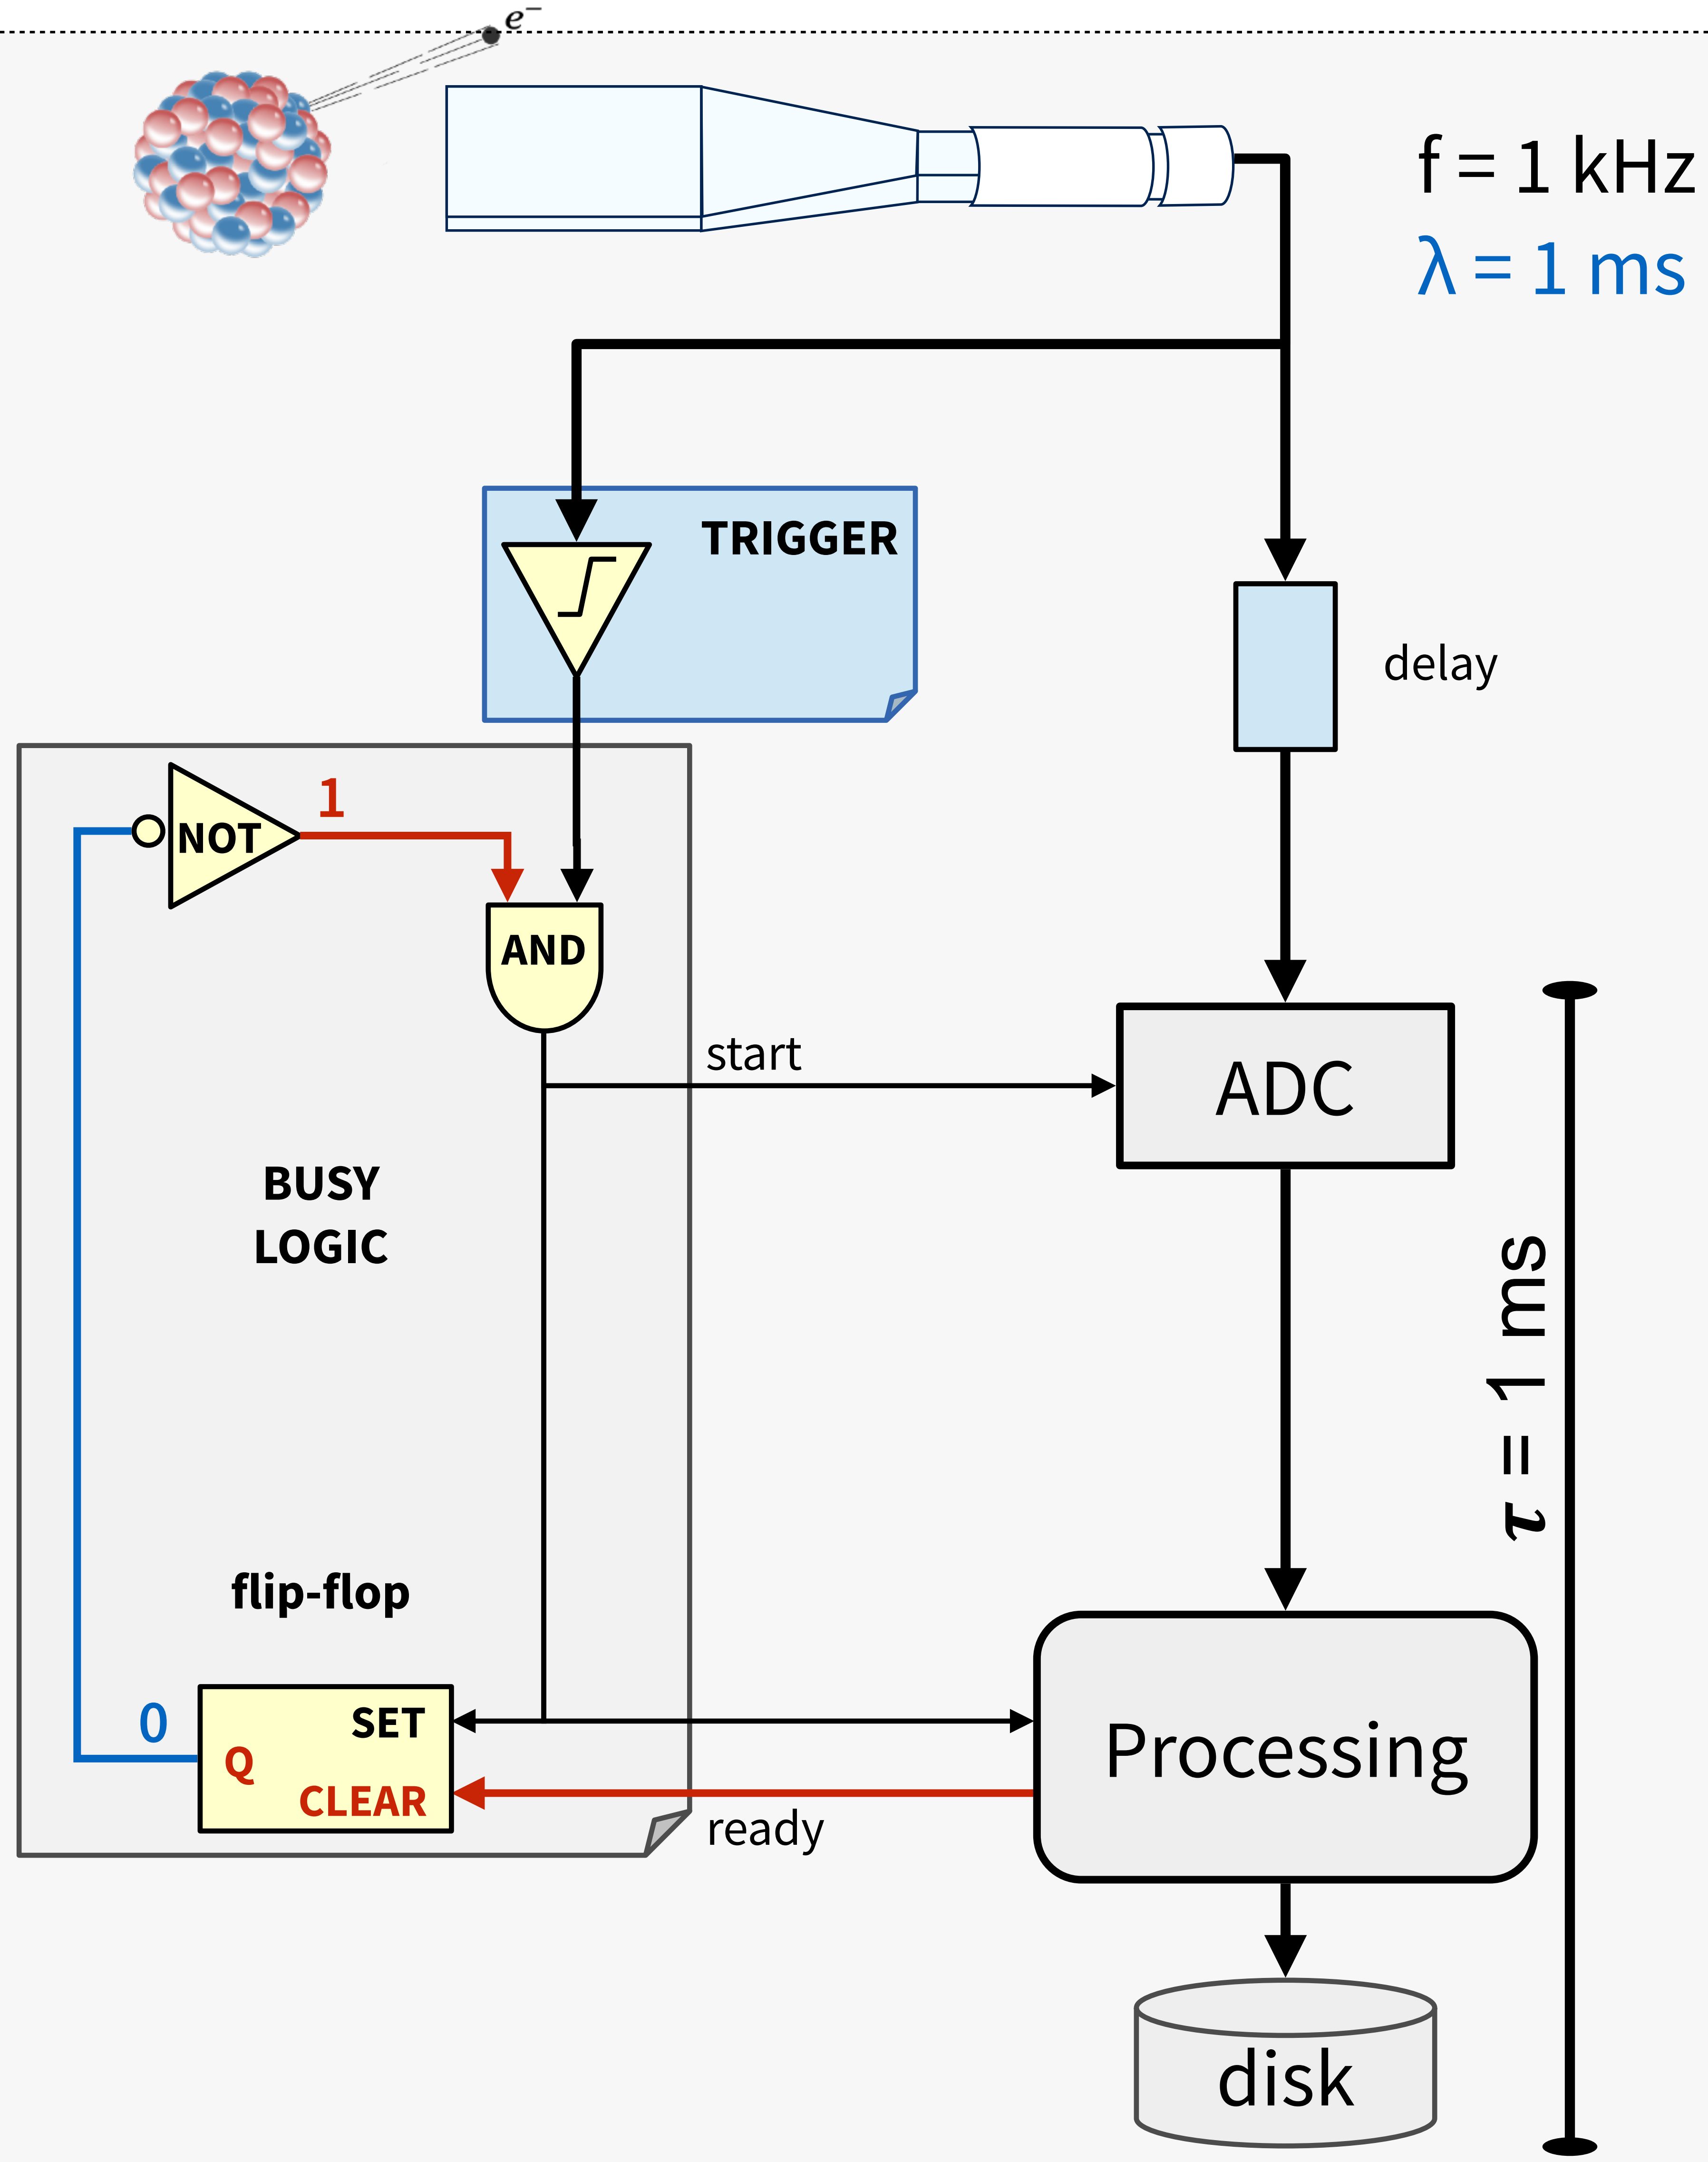
Busy logic

At the end of processing a ready signal is sent to the flip-flop

- The flip-flop flips again
- The gate is now opened
- The system is ready to accept a new trigger

i.e. busy logic avoids triggers while daq is busy in processing

- New triggers do not interfere w/ previous data



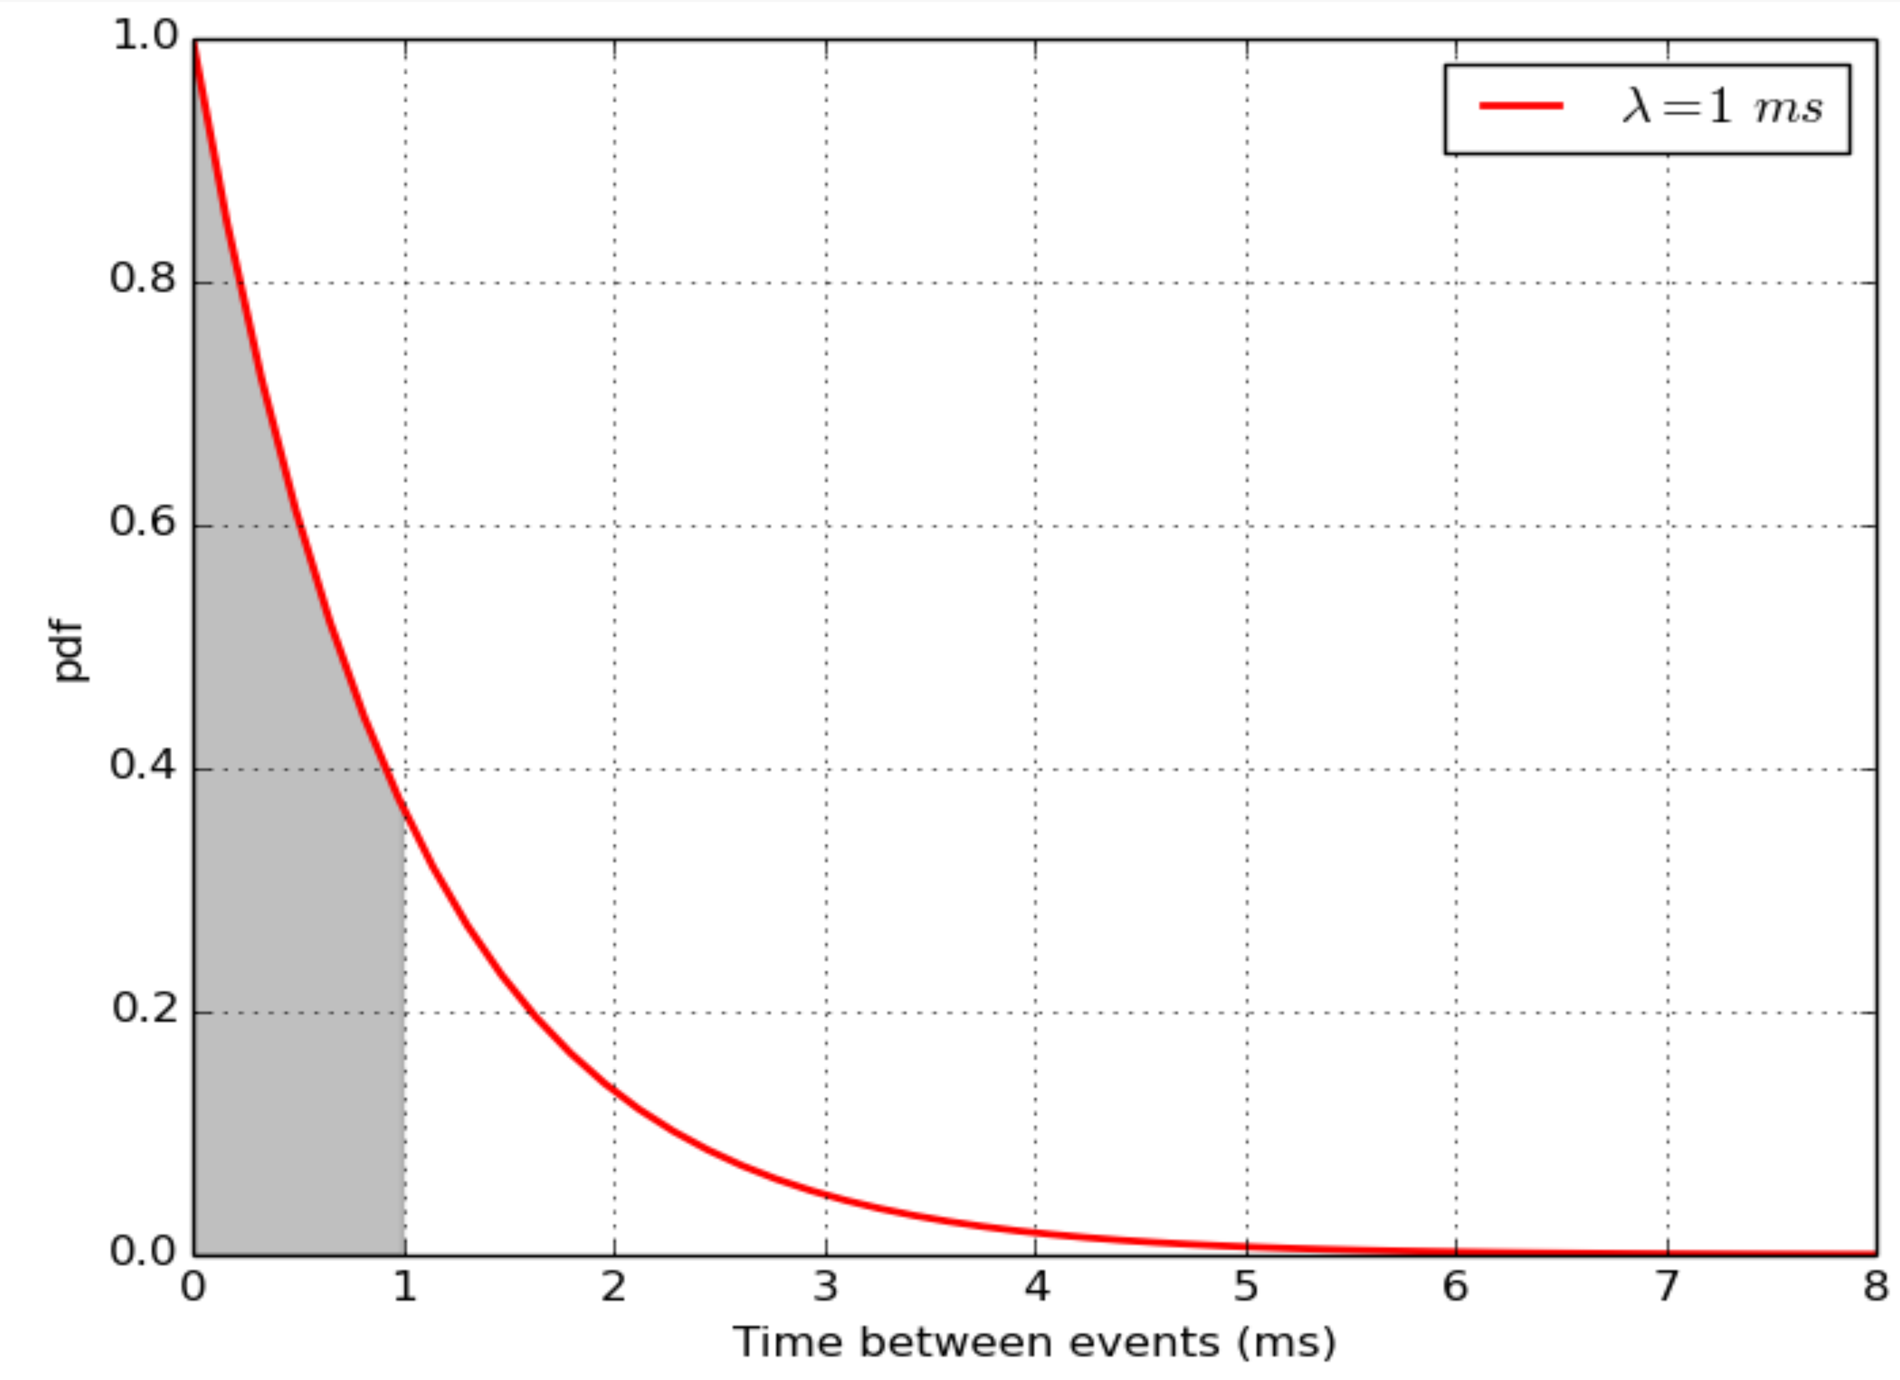
Deadtime and efficiency

So the busy logic protects electronics from unwanted triggers

- New signals are accepted only when the system in ready to process them

What (average) DAQ rate can be achieved now?

- How much we lose with the busy logic?



Reminder: with periodic triggers and $\tau = 1$ ms the limit was ***1 kHz***

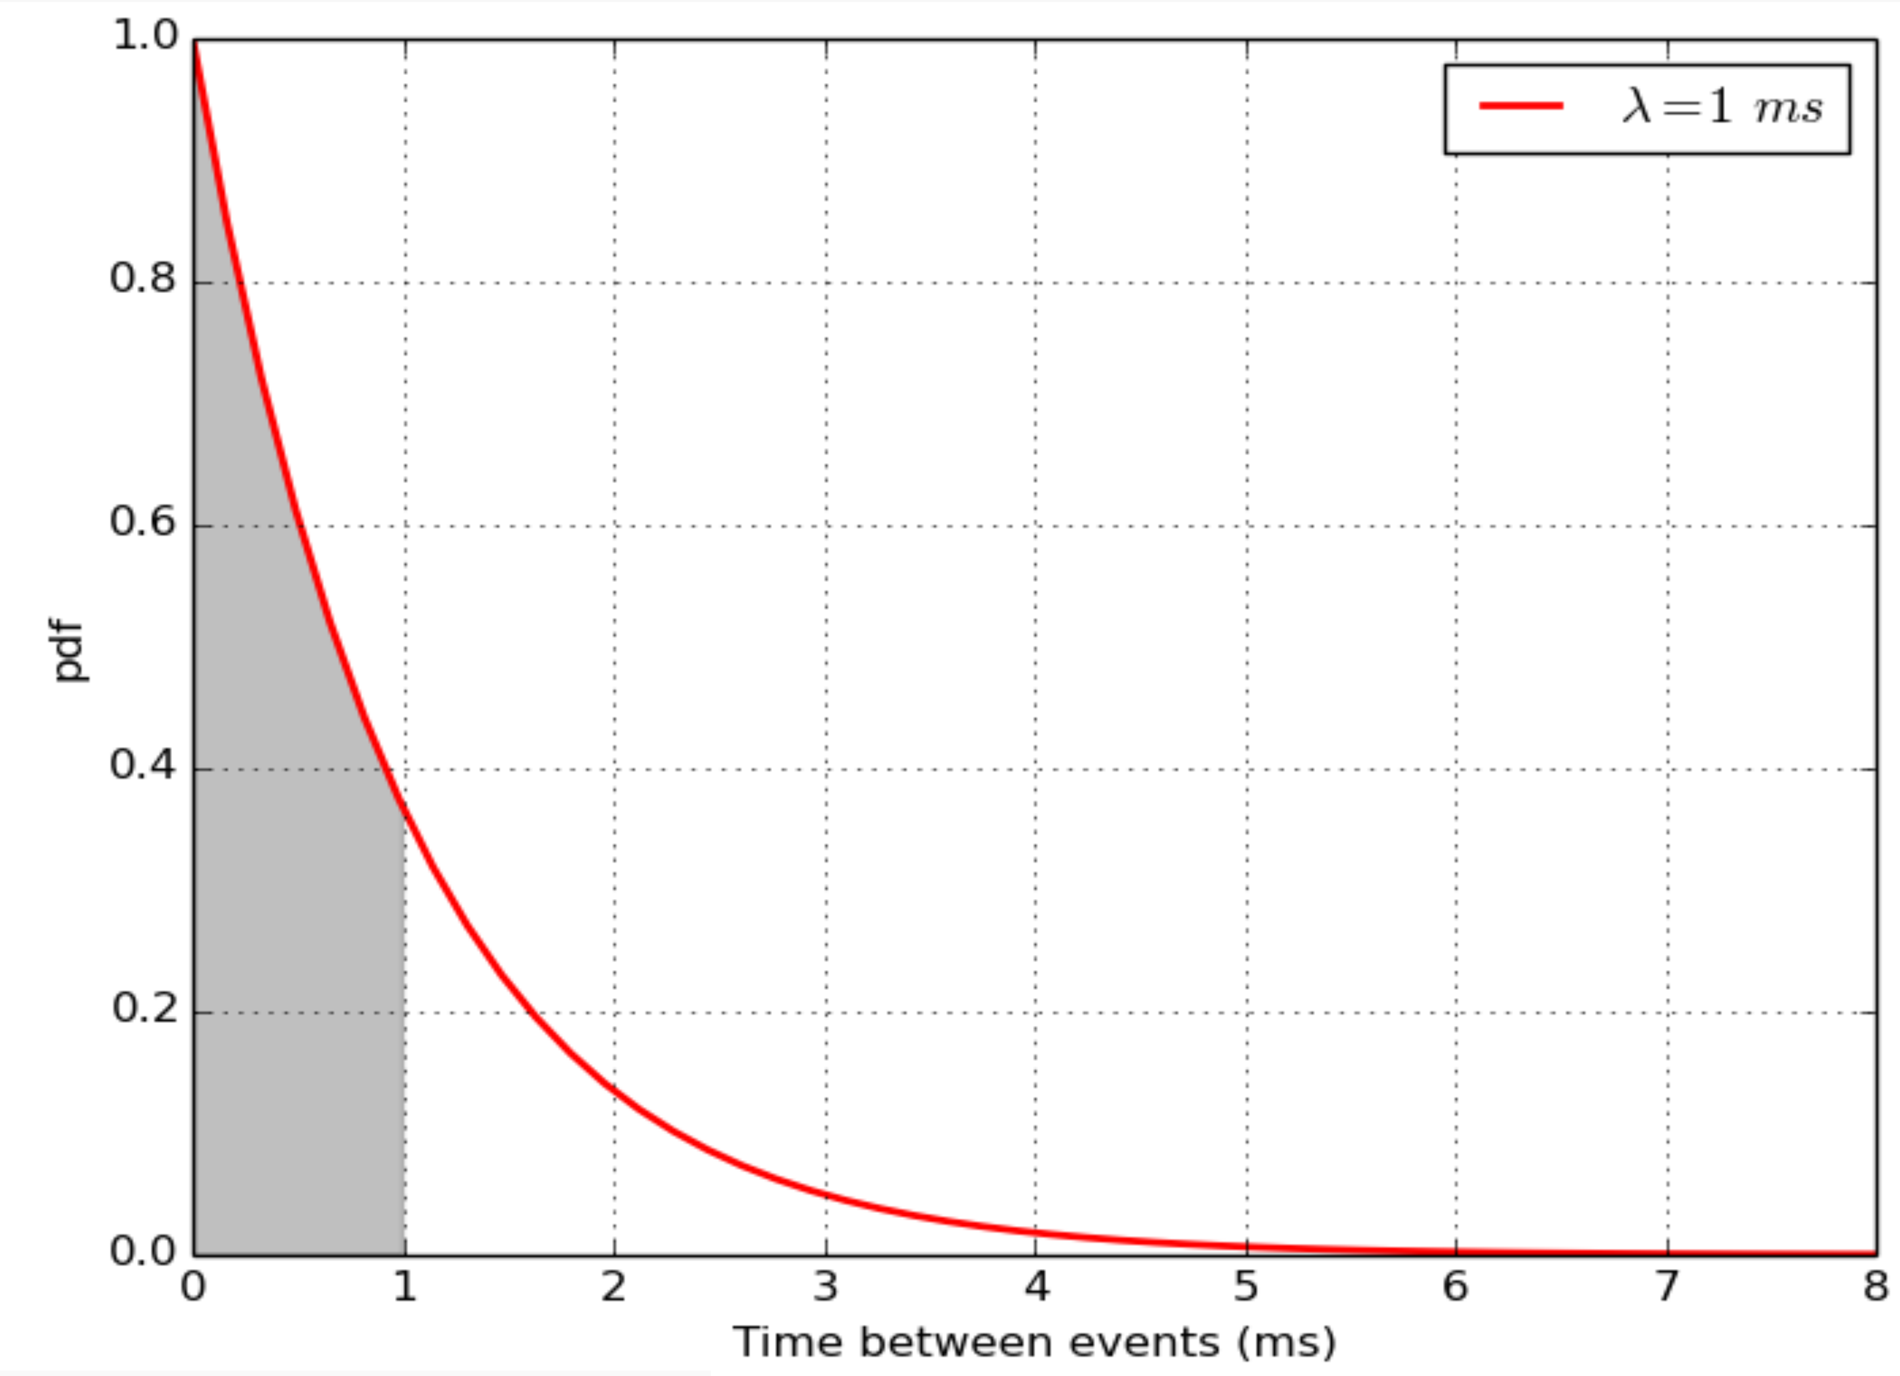
Deadtime and efficiency

Definitions

- f: average rate of physics (input)
- ν: average rate of DAQ (output)
- τ : **deadtime**, needed to process an event, without being able to handle other triggers
- probabilities: P[busy] = $\nu\tau$; P[free] = 1 - $\nu\tau$

Therefore:

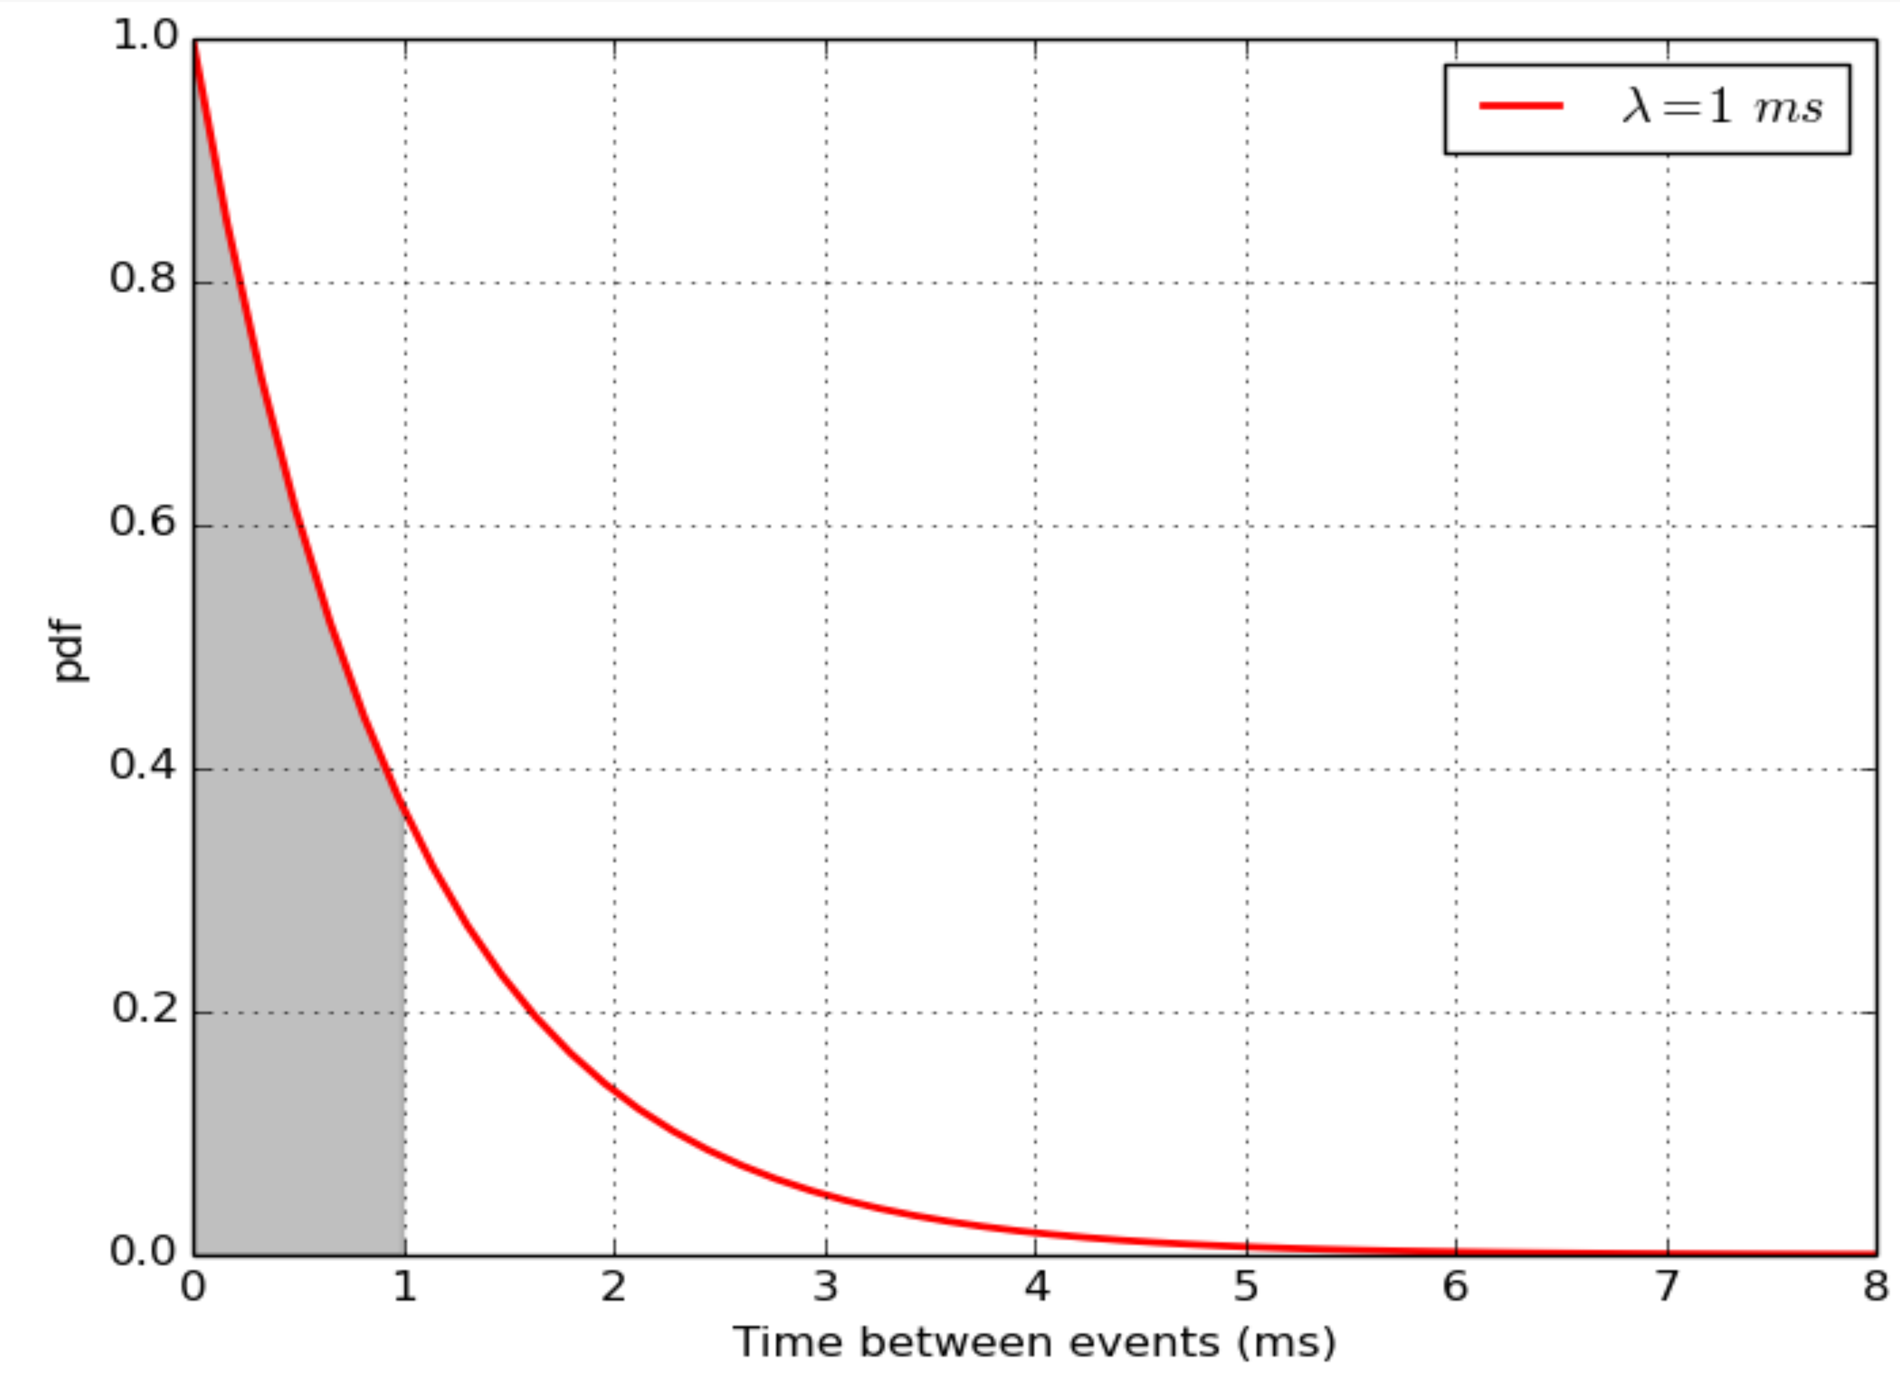
$$\nu = fP[free] \Rightarrow \nu = f(1 - \nu\tau) \Rightarrow \nu = \frac{f}{1 + f\tau}$$



Deadtime and efficiency

Definitions

- f: average rate of physics (input)
- ν: average rate of DAQ (output)
- τ : **deadtime**, needed to process an event, without being able to handle other triggers
- probabilities: P[busy] = $\nu\tau$; P[free] = 1 - $\nu\tau$



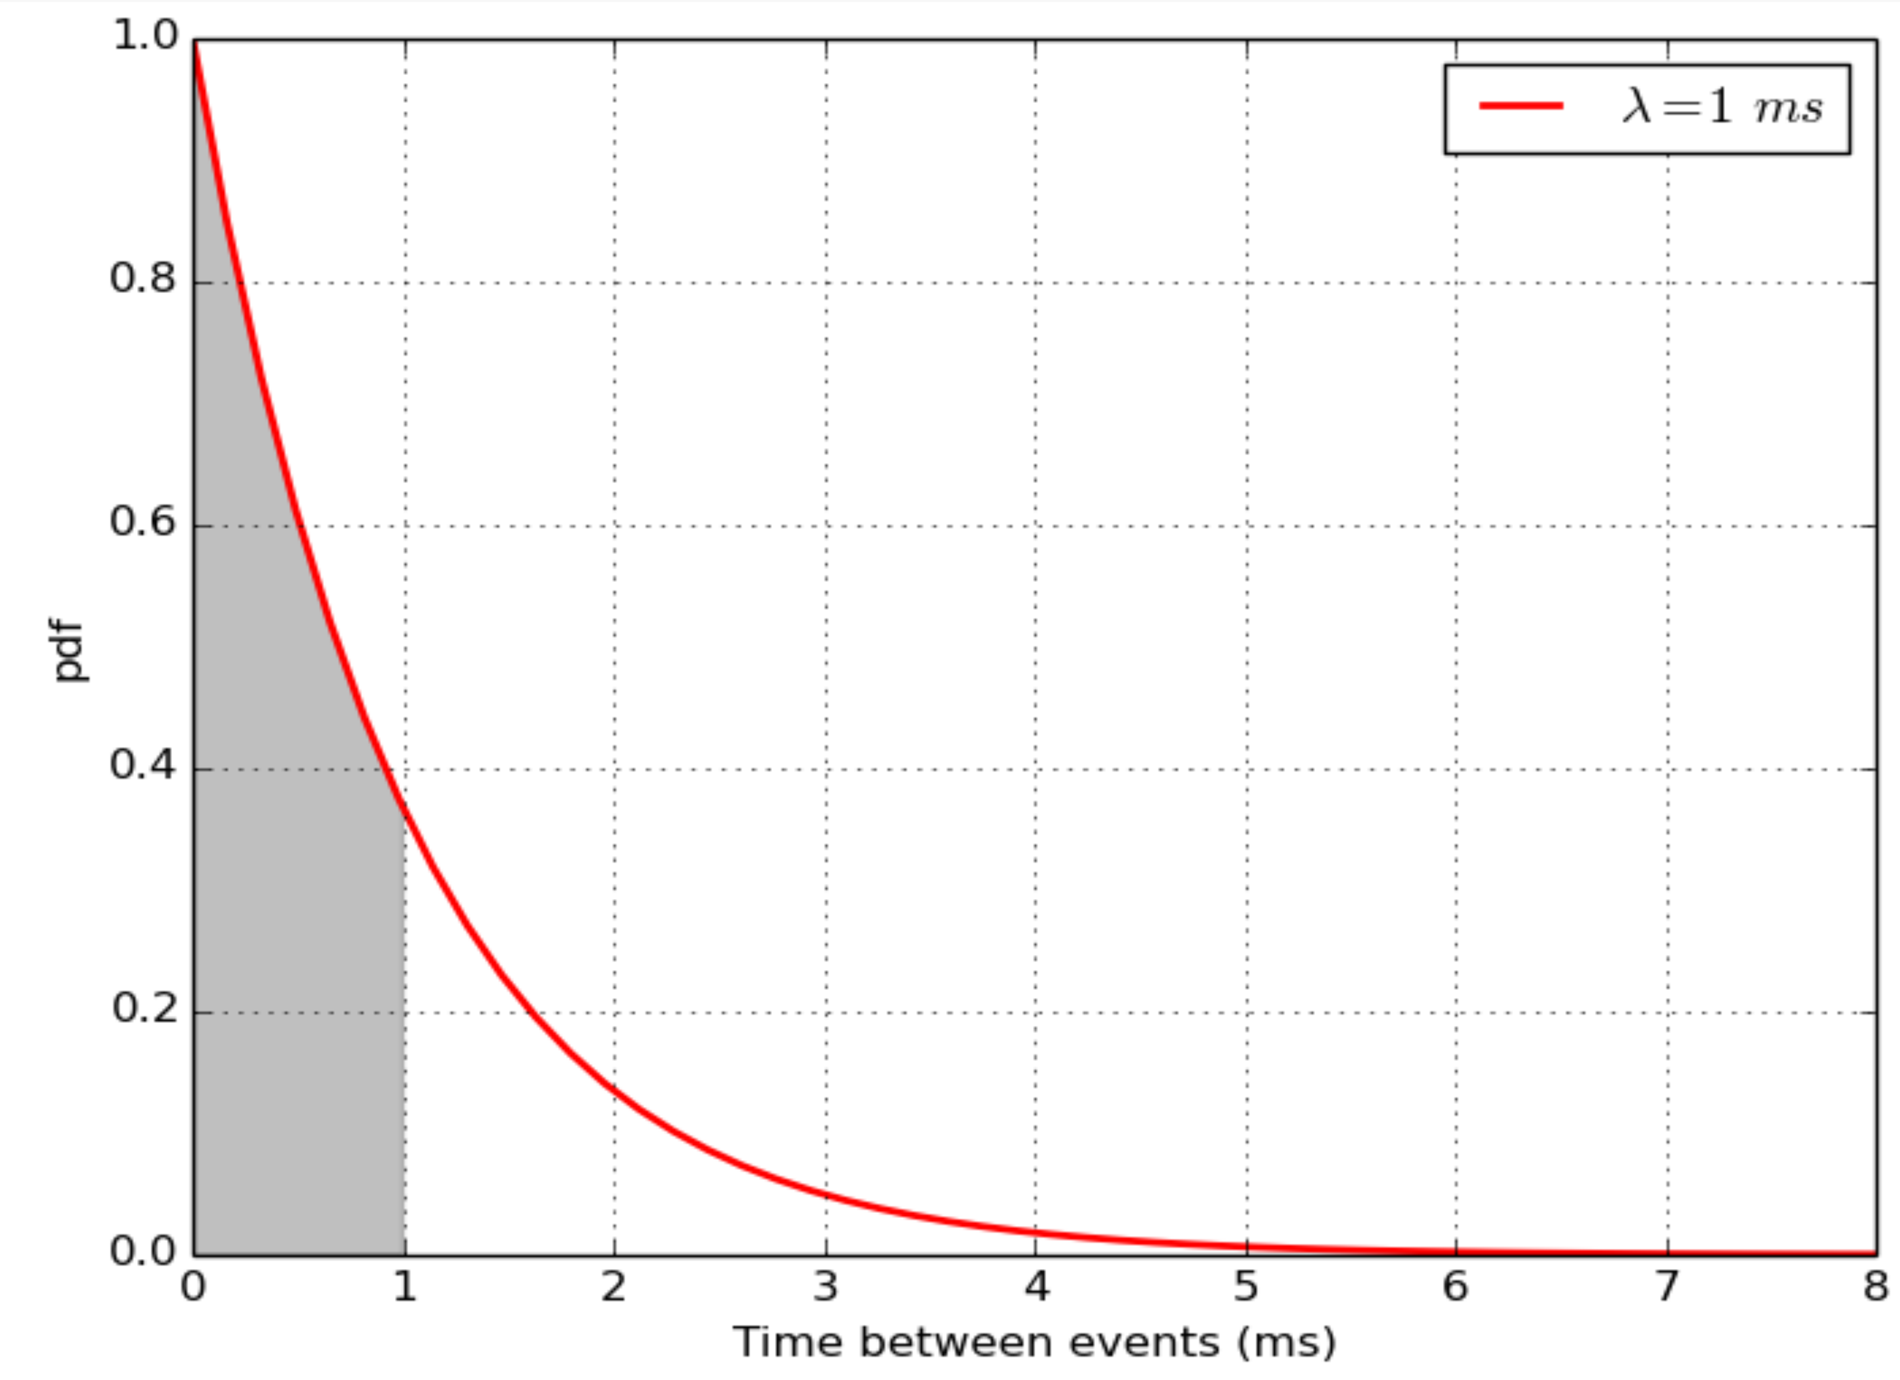
Therefore:

$$\nu = fP[free] \Rightarrow \nu = f(1 - \nu\tau) \Rightarrow \nu = \frac{f}{1 + f\tau}$$

Deadtime and efficiency

Definitions

- f: average rate of physics (input)
- ν: average rate of DAQ (output)
- τ: **deadtime**, needed to process an event, without being able to handle other triggers
- probabilities: P[busy] = $\nu\tau$; P[free] = $1-\nu\tau$



Therefore:

$$\nu = fP[free] \Rightarrow \nu = f(1-\nu\tau) \Rightarrow \nu = \frac{f}{1+f\tau}$$

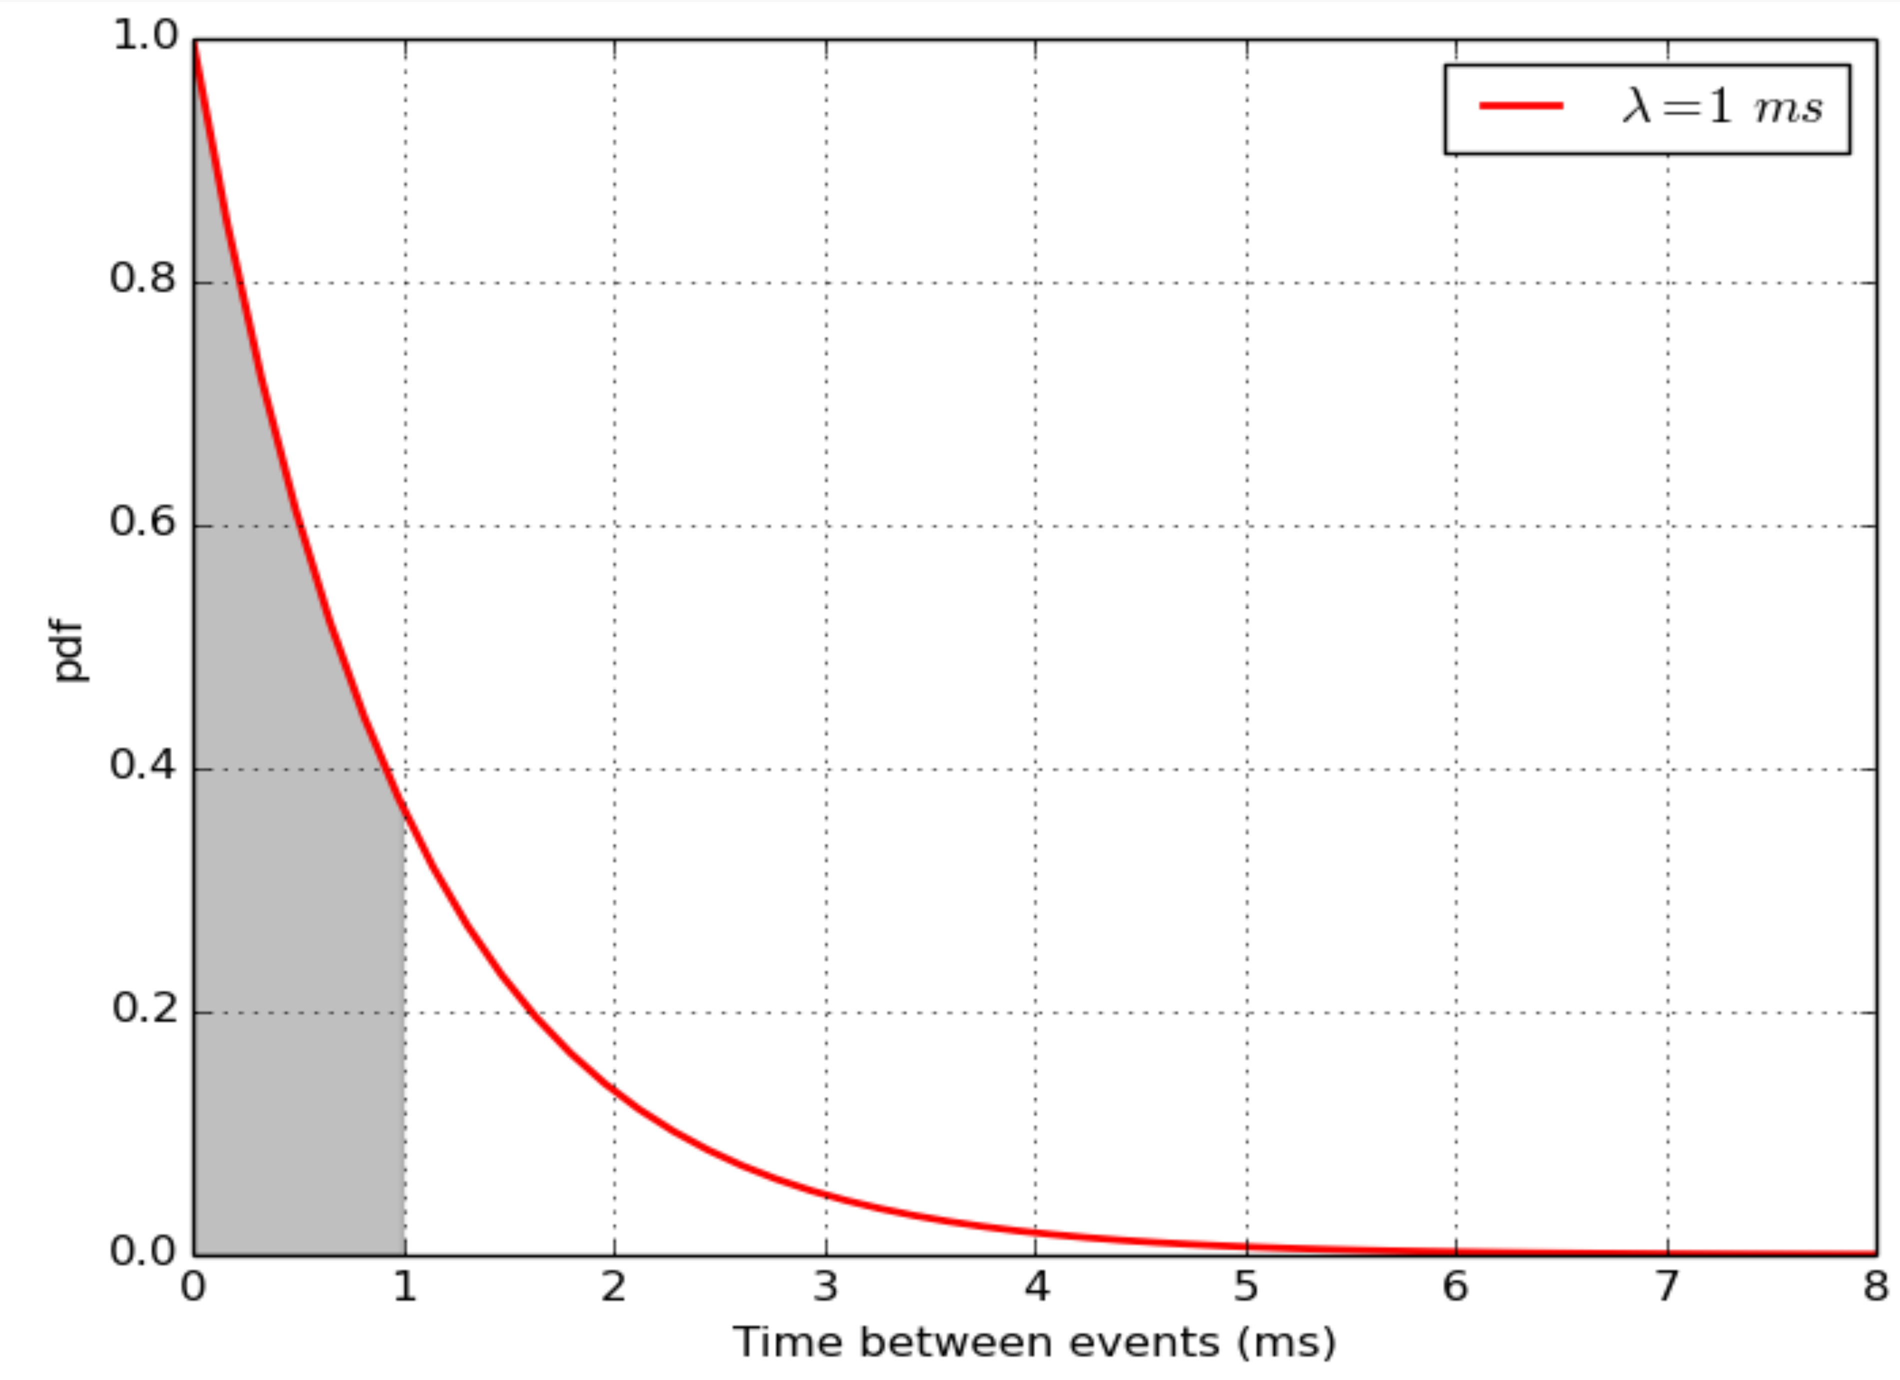
Deadtime and efficiency

Definitions

- f: average rate of physics (input)
- ν: average rate of DAQ (output)
- τ : **deadtime**, needed to process an event, without being able to handle other triggers
- probabilities: P[busy] = $\nu\tau$;   P[free] = $1 - \nu\tau$

Therefore:

$$\nu = fP[free] \Rightarrow \nu = f(1 - \nu\tau) \Rightarrow \nu = \frac{f}{1 + f\tau}$$



Deadtime and efficiency

Due to stochastic fluctuations

- DAQ rate always < physics rate
- Efficiency always < 100%

$$\nu = \frac{f}{1 + f\tau} < f$$

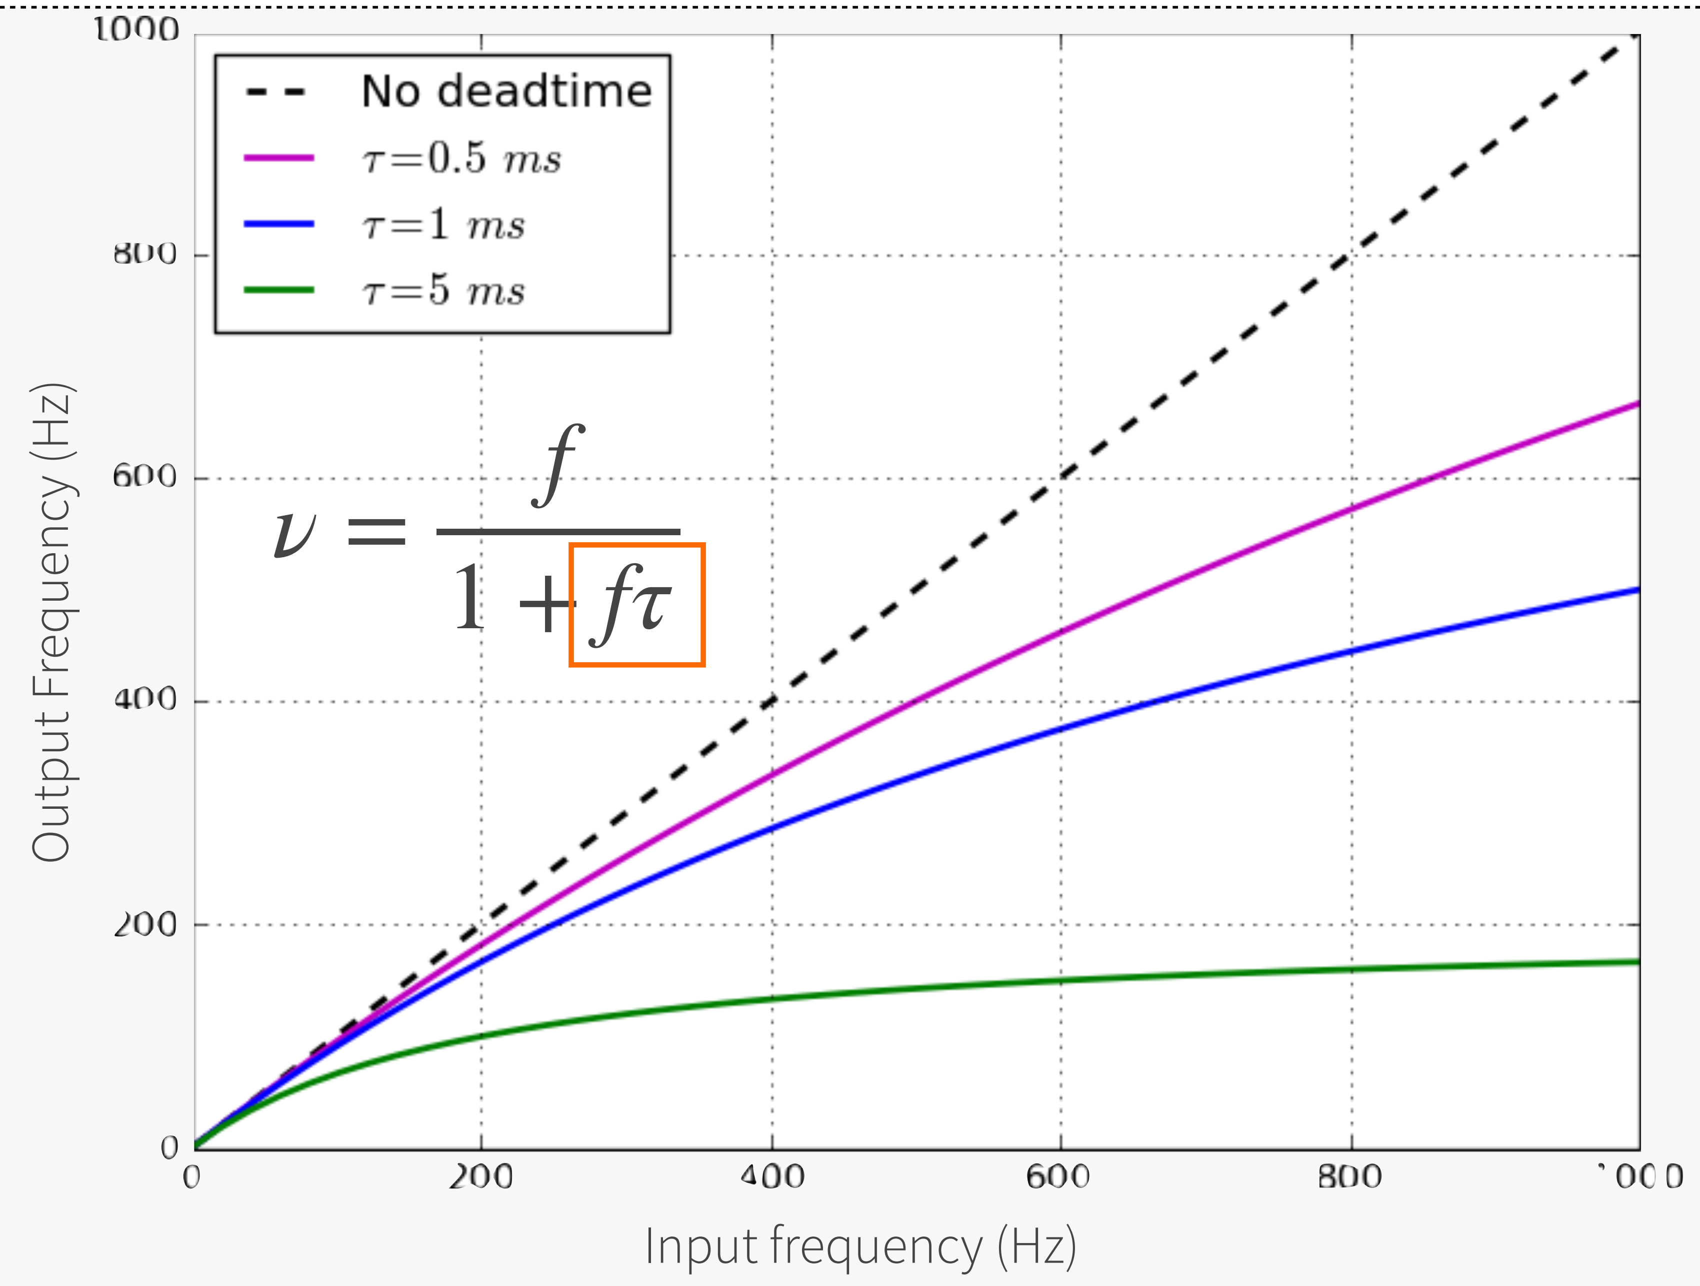
$$\epsilon = \frac{N_{saved}}{N_{tot}} = \frac{1}{1 + f\tau} < 100\,\%$$

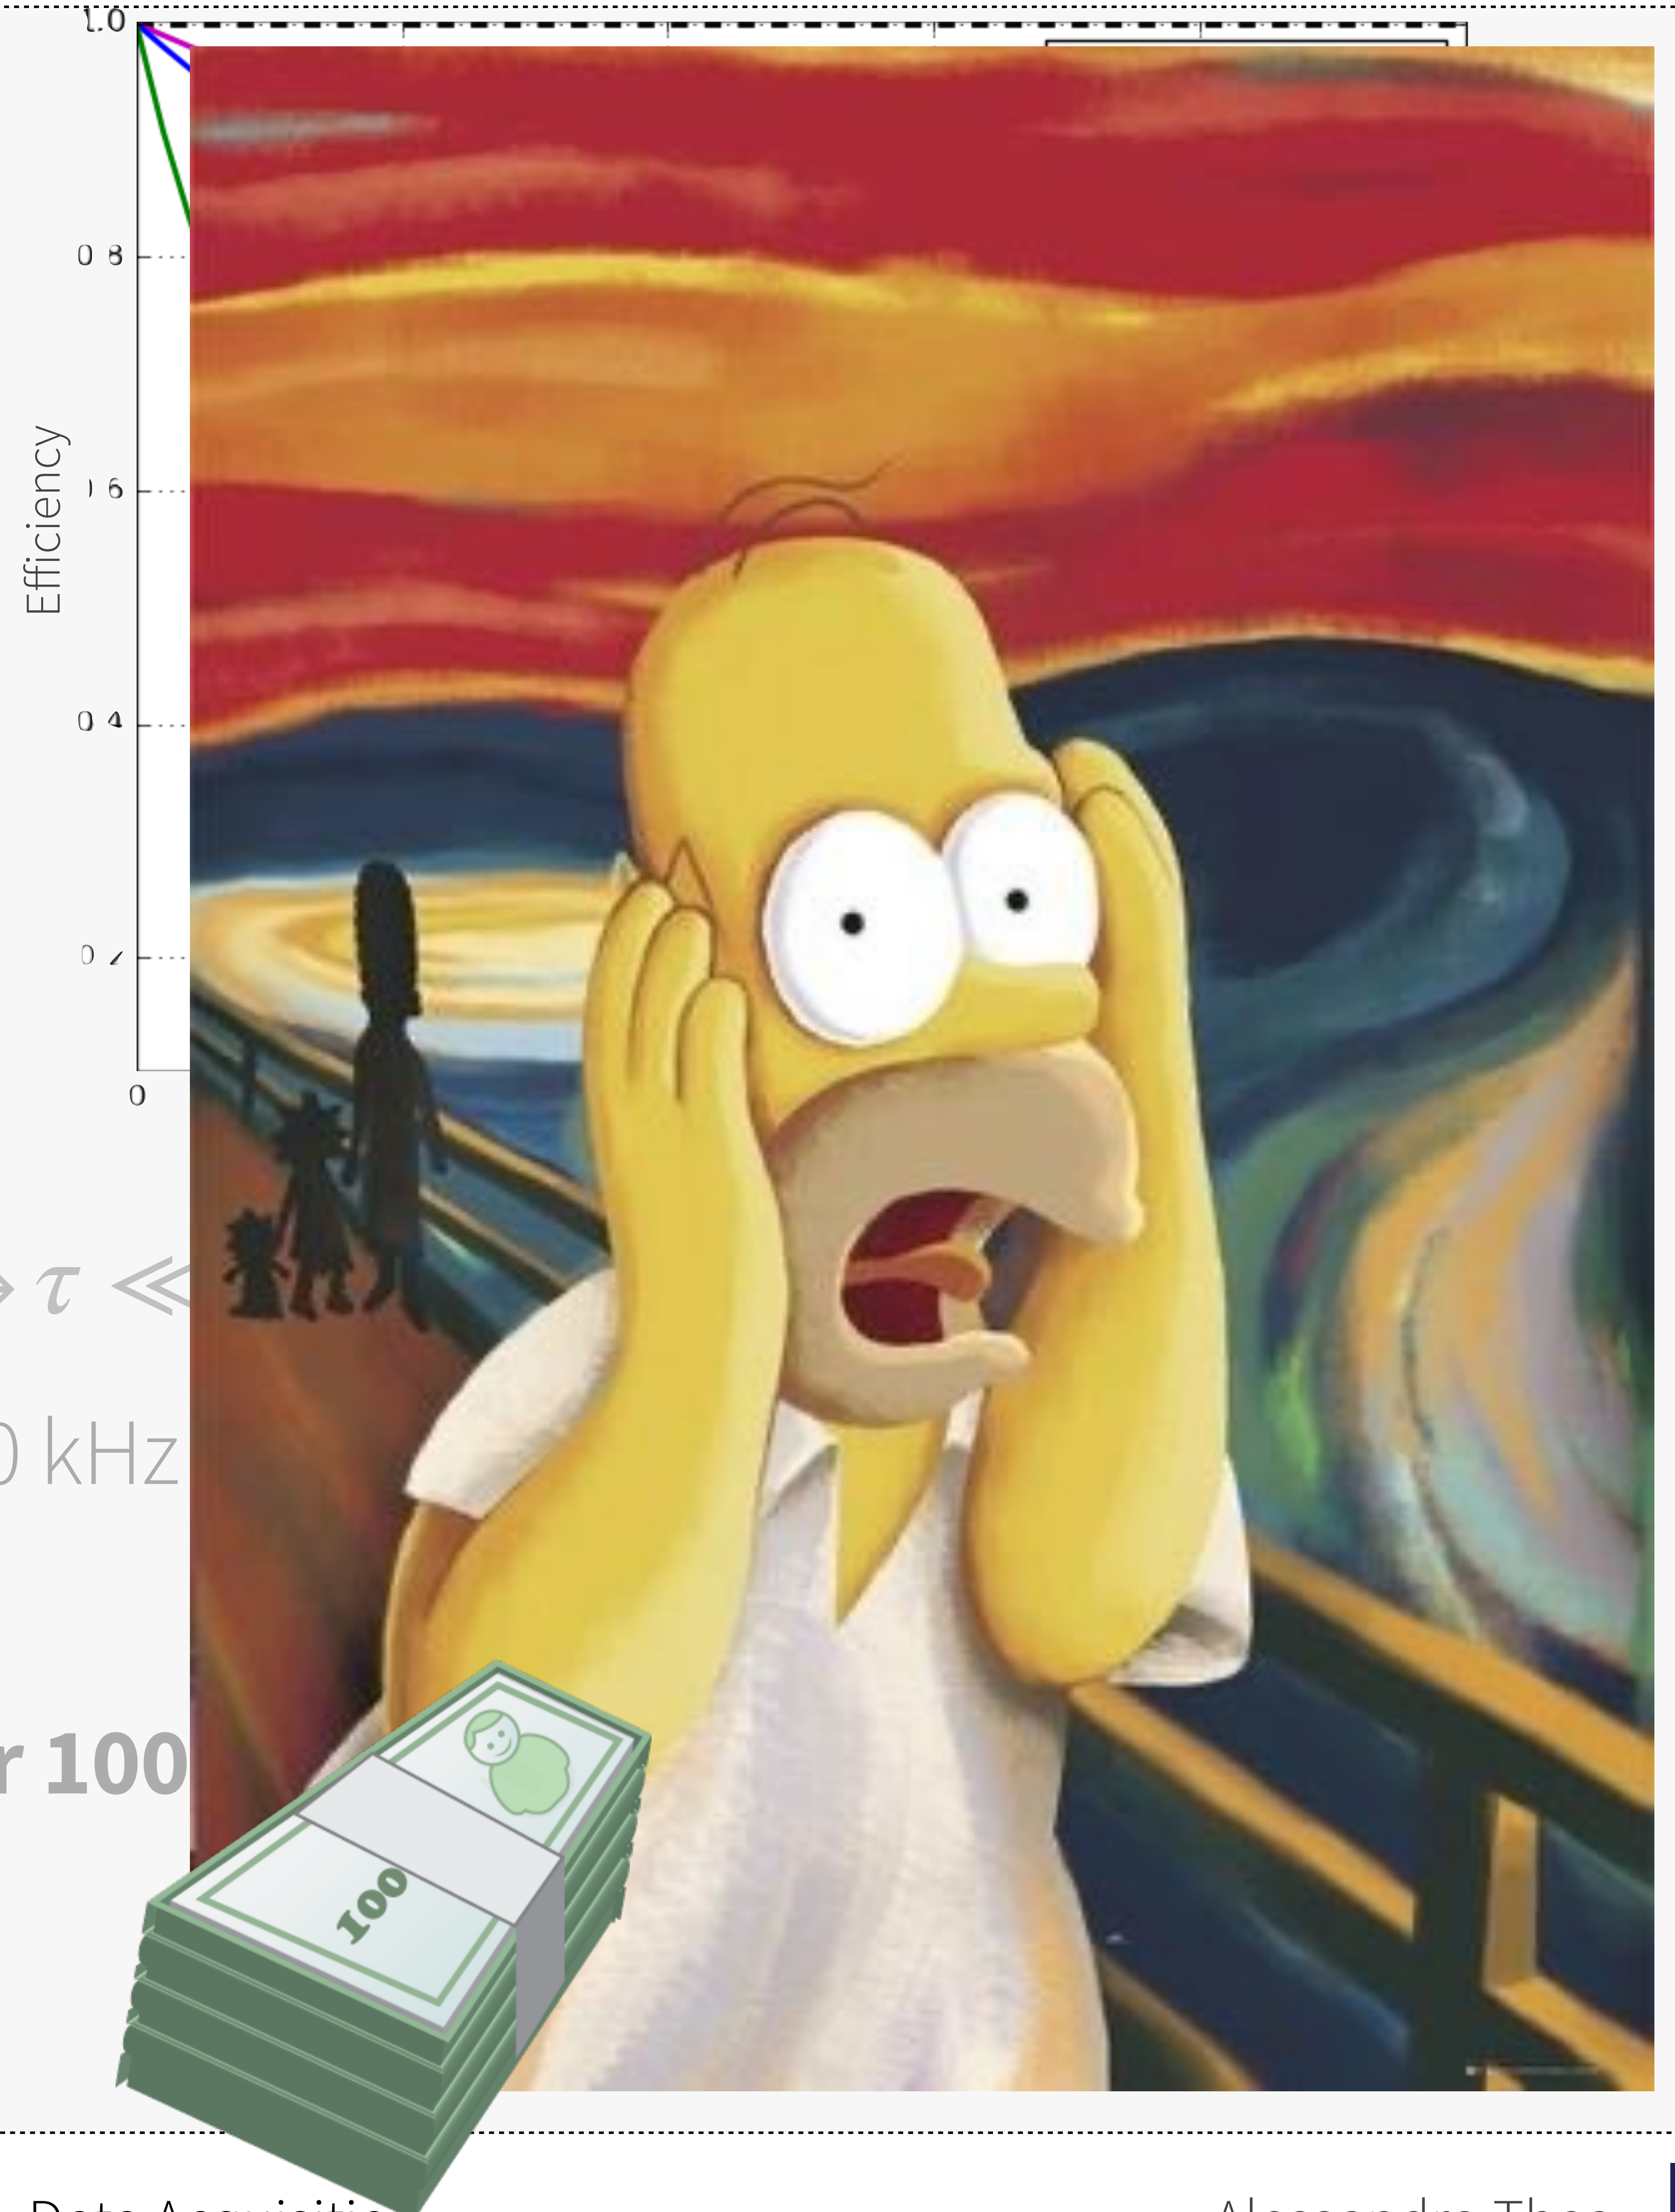
So, in our specific example

- Physics rate 1 kHz
- Deadtime 1 ms

$$f = 1\ kHz \quad \tau = 1\ ms \;\Rightarrow\; \nu = 500\ Hz \quad \epsilon = 50\,\%$$

Deadtime and efficiency





In order to obtain $\epsilon \simeq$ 100% (i.e.: $\nu \simeq \tau$) $\rightarrow f\tau \ll 1 \rightarrow \tau \ll$

- E.g.: $\epsilon \simeq$ 99% for f = 1 kHz $\rightarrow \tau$ < 0.01 ms $\rightarrow 1/\tau$ > 100 kHz
- To cope with the input signal fluctuations, we have to **over-design** our DAQ system by a **factor 100**

How can we mitigate this effect?

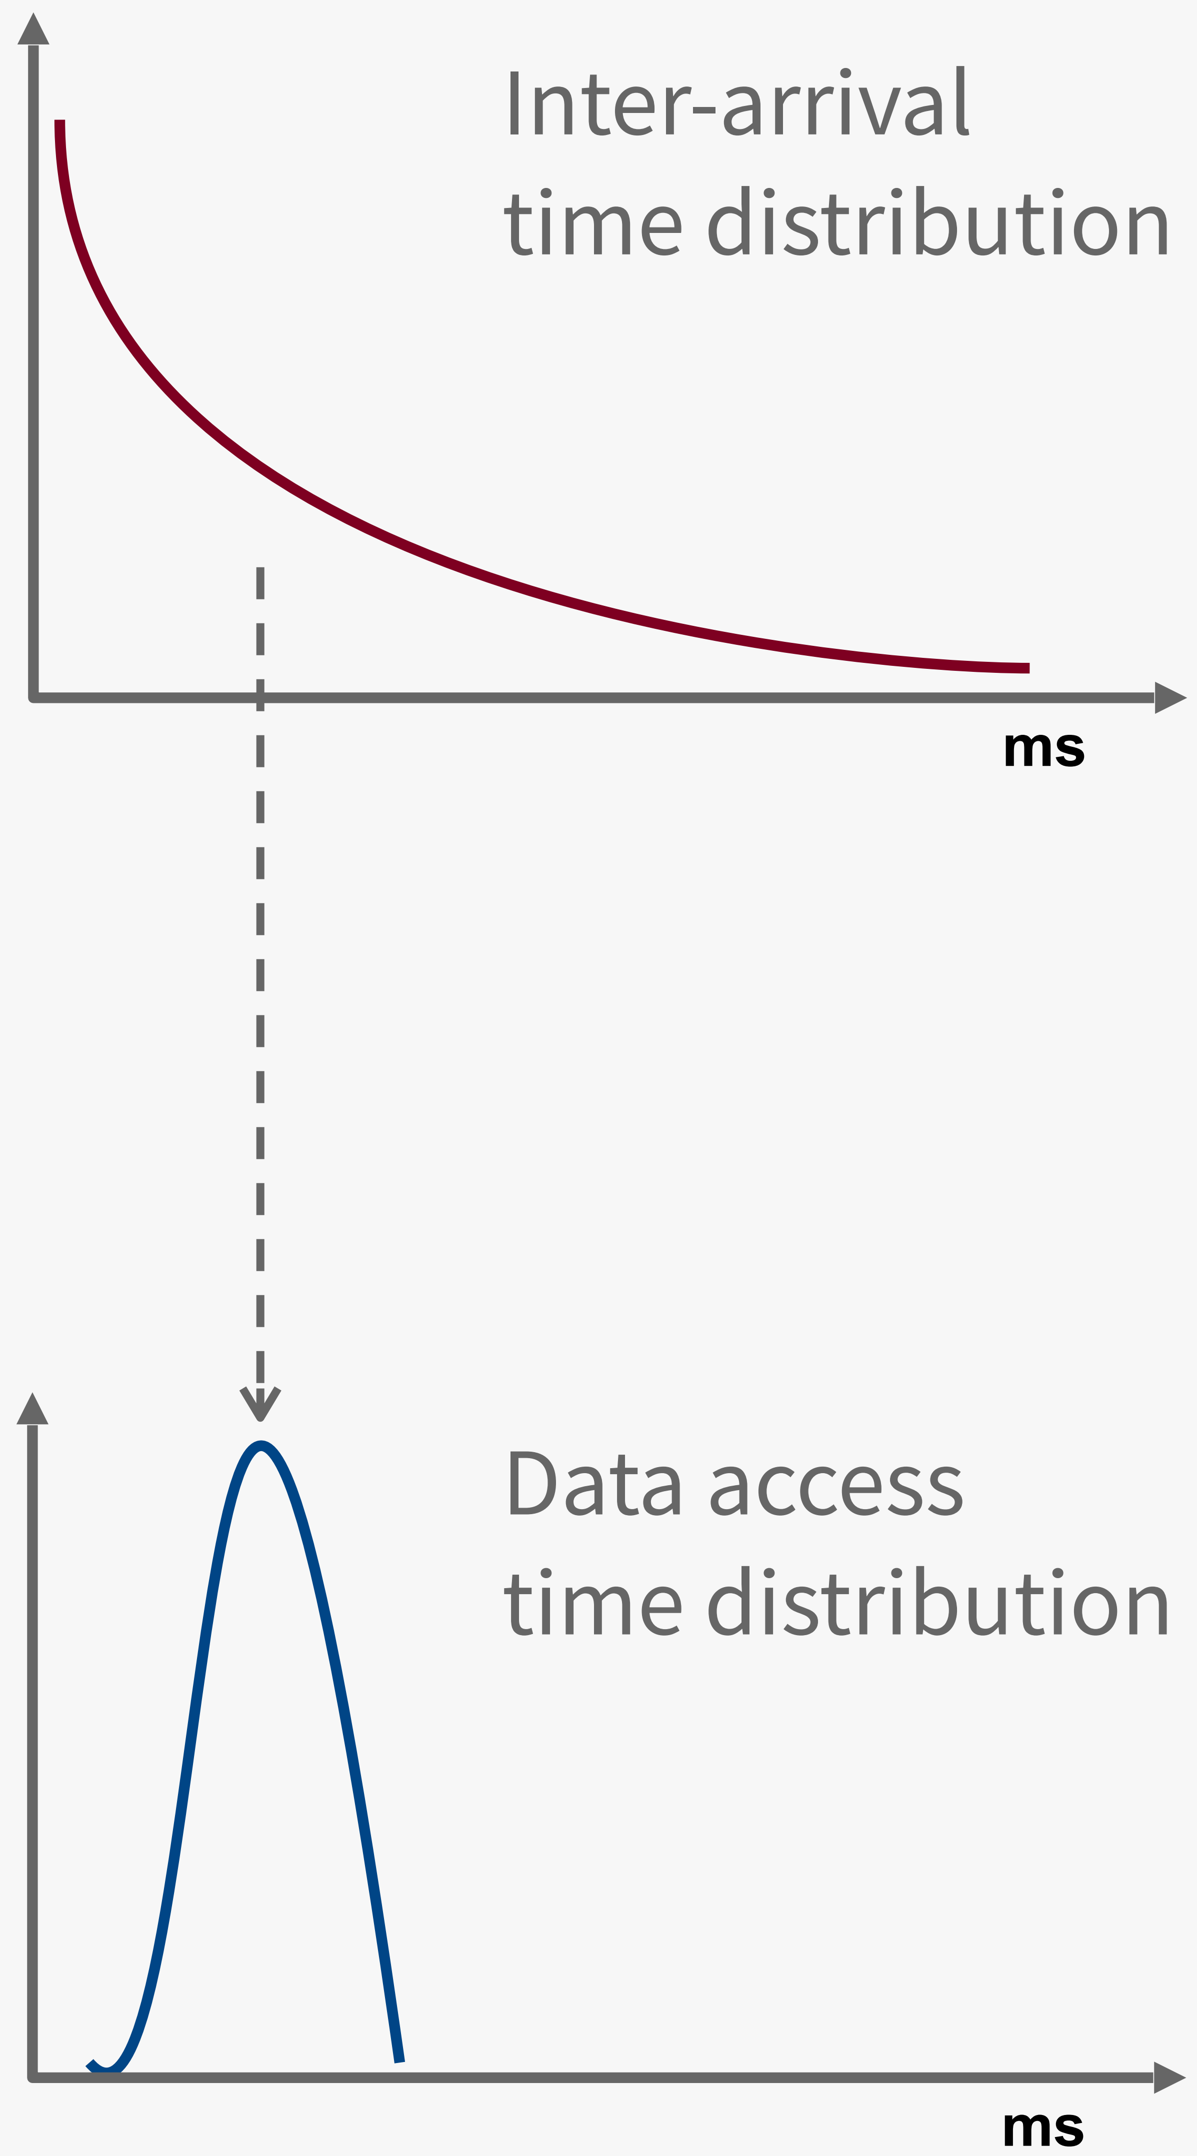
De-randomization

What if we were able to make the system more **deterministic** and less dependent on the arrival time of our signals?

- Then we could ensure that events don't arrive when the system is busy
- This is called **de-randomization**

How it can be achieved?

- by **buffering** the data (introducing a holding queue where it can wait to be processed)



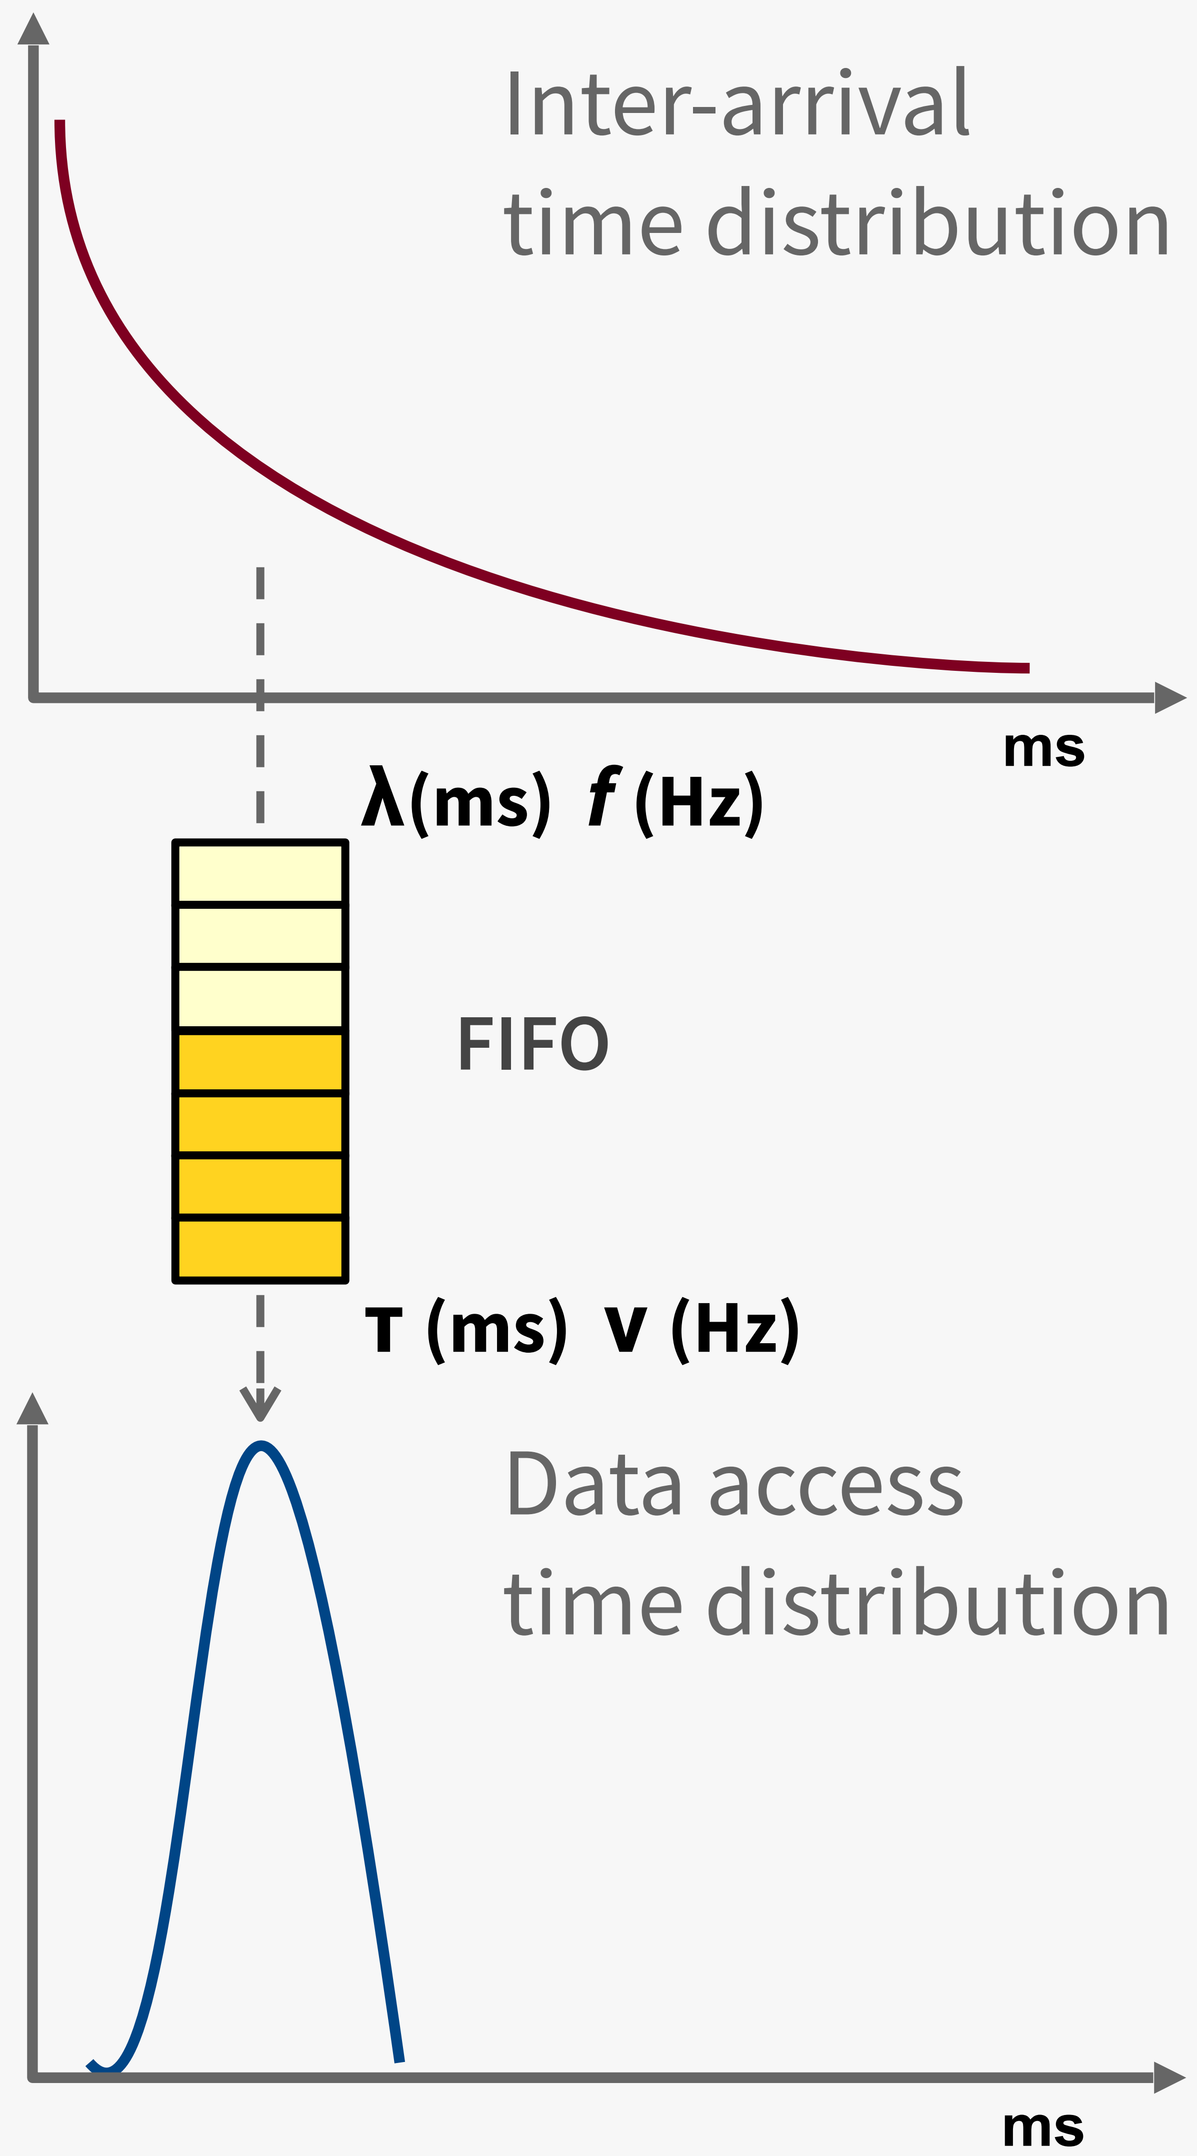
De-randomization

What if we were able to make the system more **deterministic** and less dependent on the arrival time of our signals?

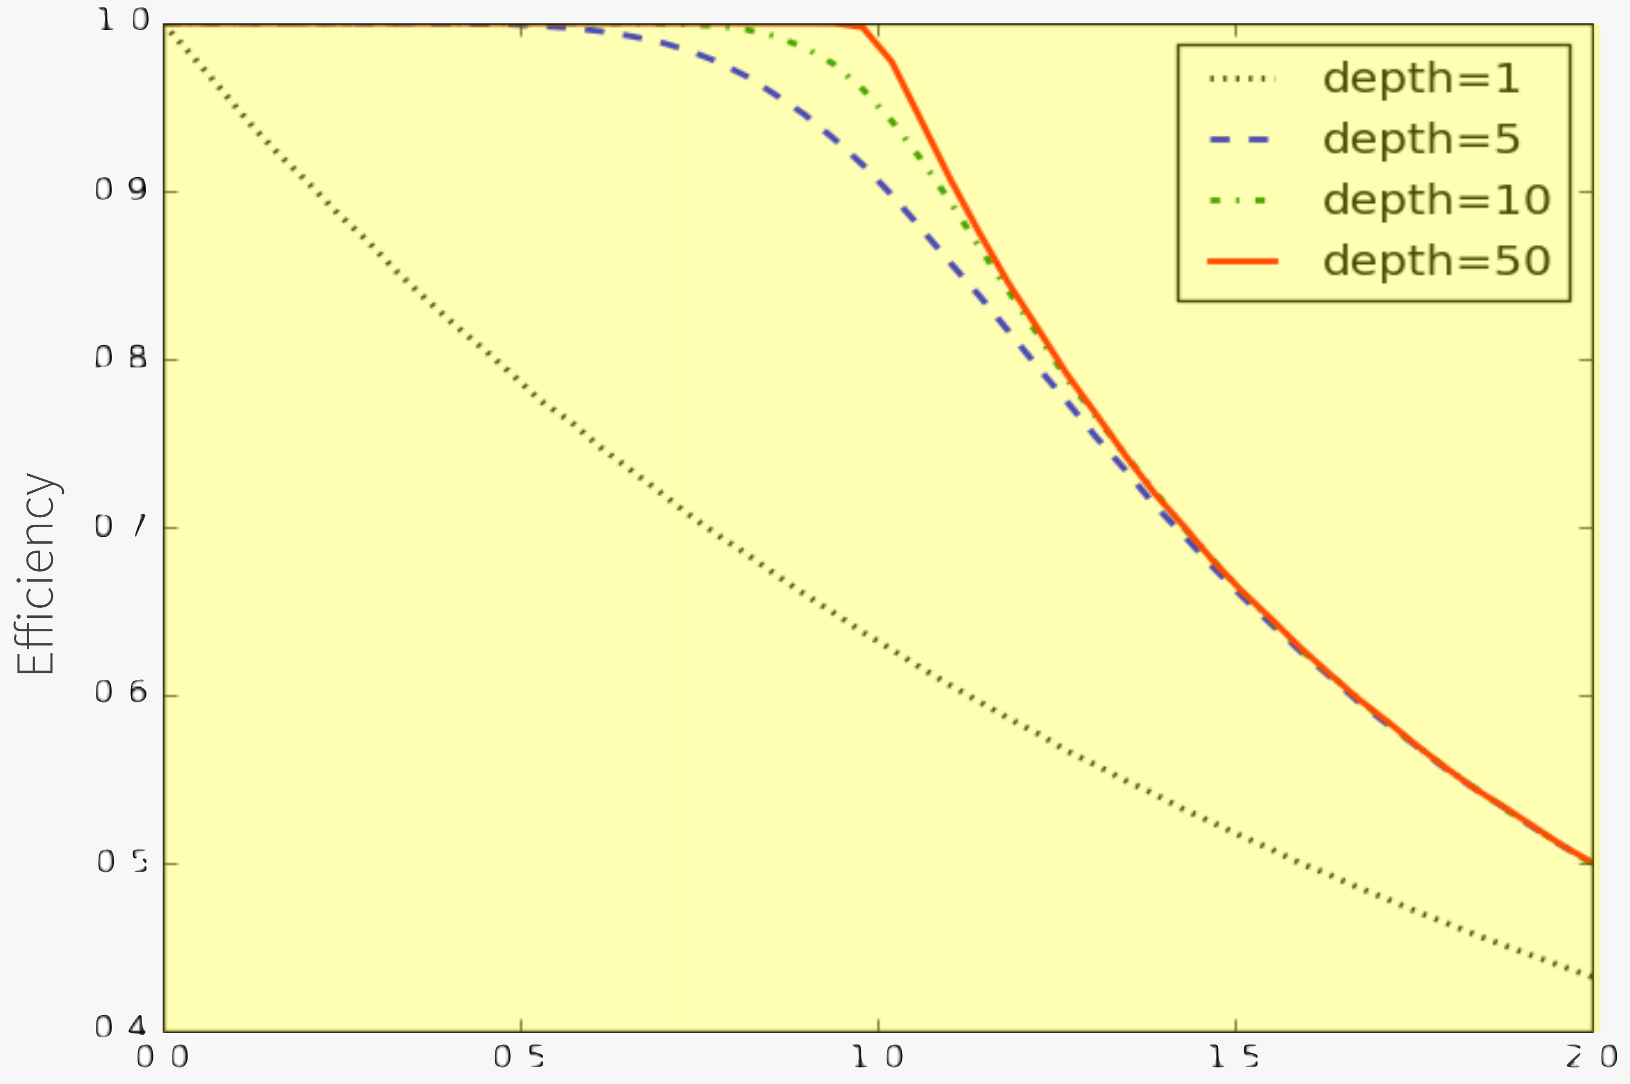
- Then we could ensure that events don't arrive when the system is busy
- This is called **de-randomization**

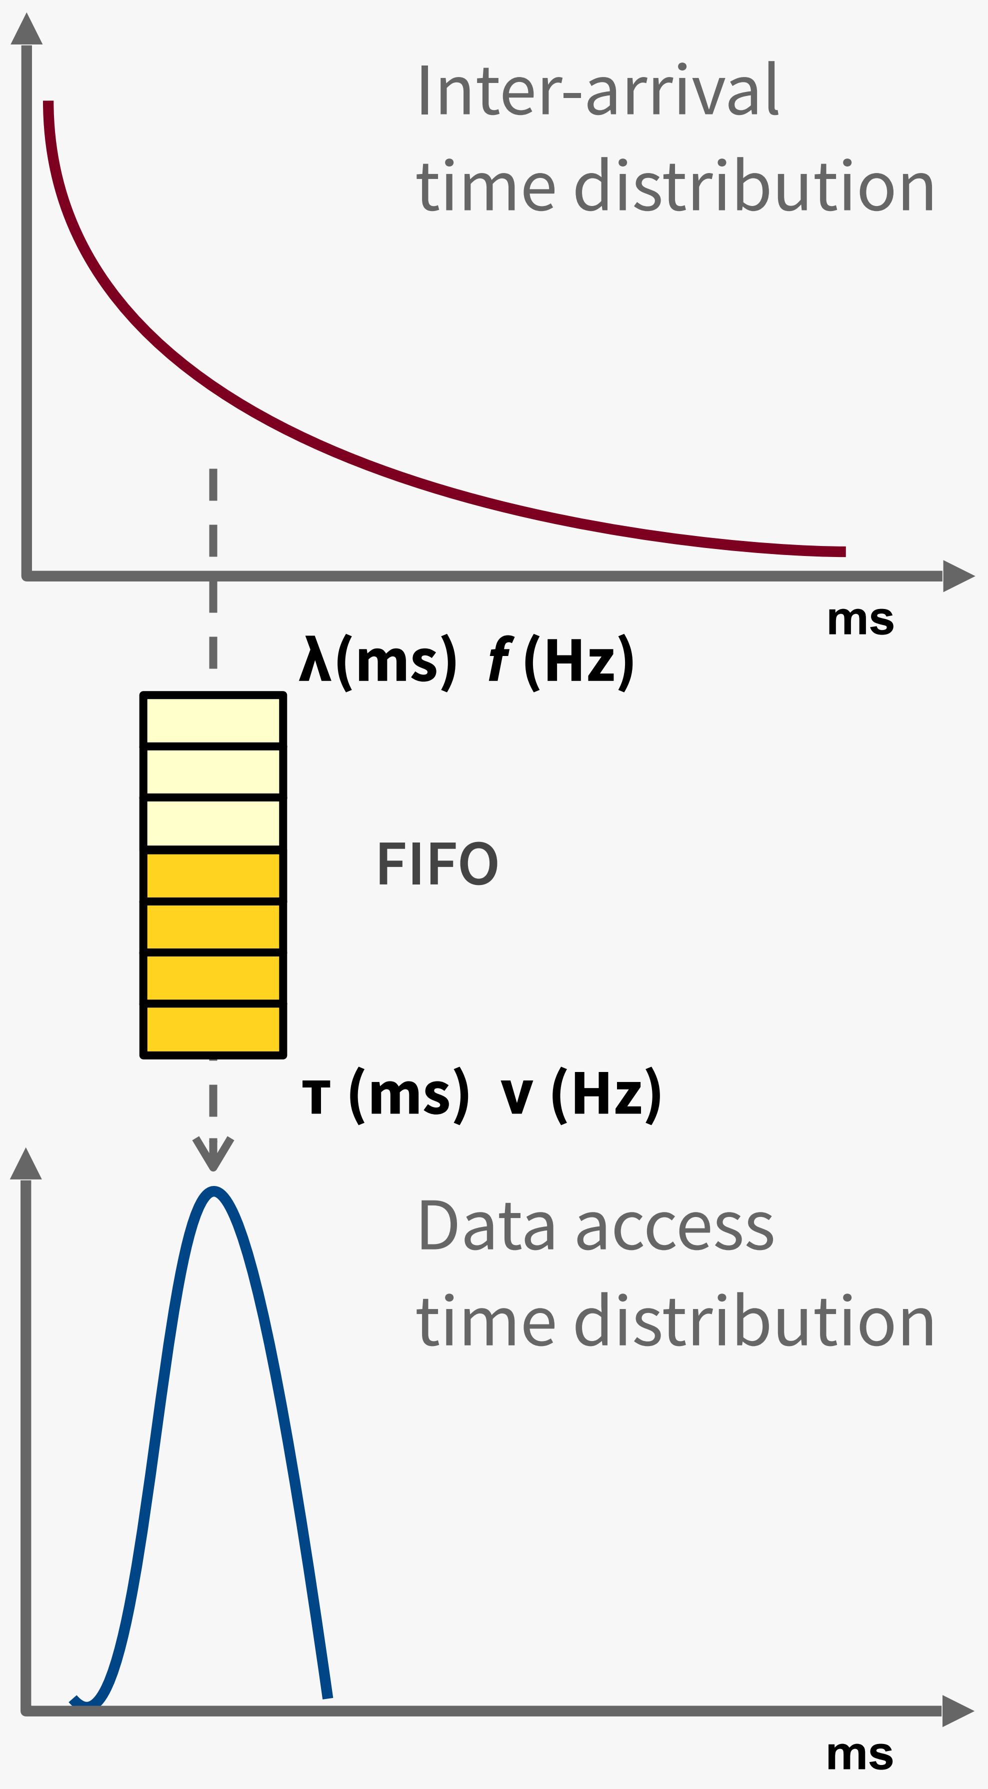
How it can be achieved?

- by **buffering** the data: introducing a holding queue where it can wait to be processed



Queuing theory





Efficiency vs traffic intensity ($\rho = \tau/\lambda$) for different queue depths

- ρ ≪ 1: the output is over-designed ($\tau \ll \lambda$)
- ρ > 1: the system is overloaded ($\tau > \lambda$)
- ρ ~ 1: using a queue, high efficiency obtained even w/ moderate depth

Analytic calculation possible for very simple systems only

- Otherwise MonteCarlo simulation is required

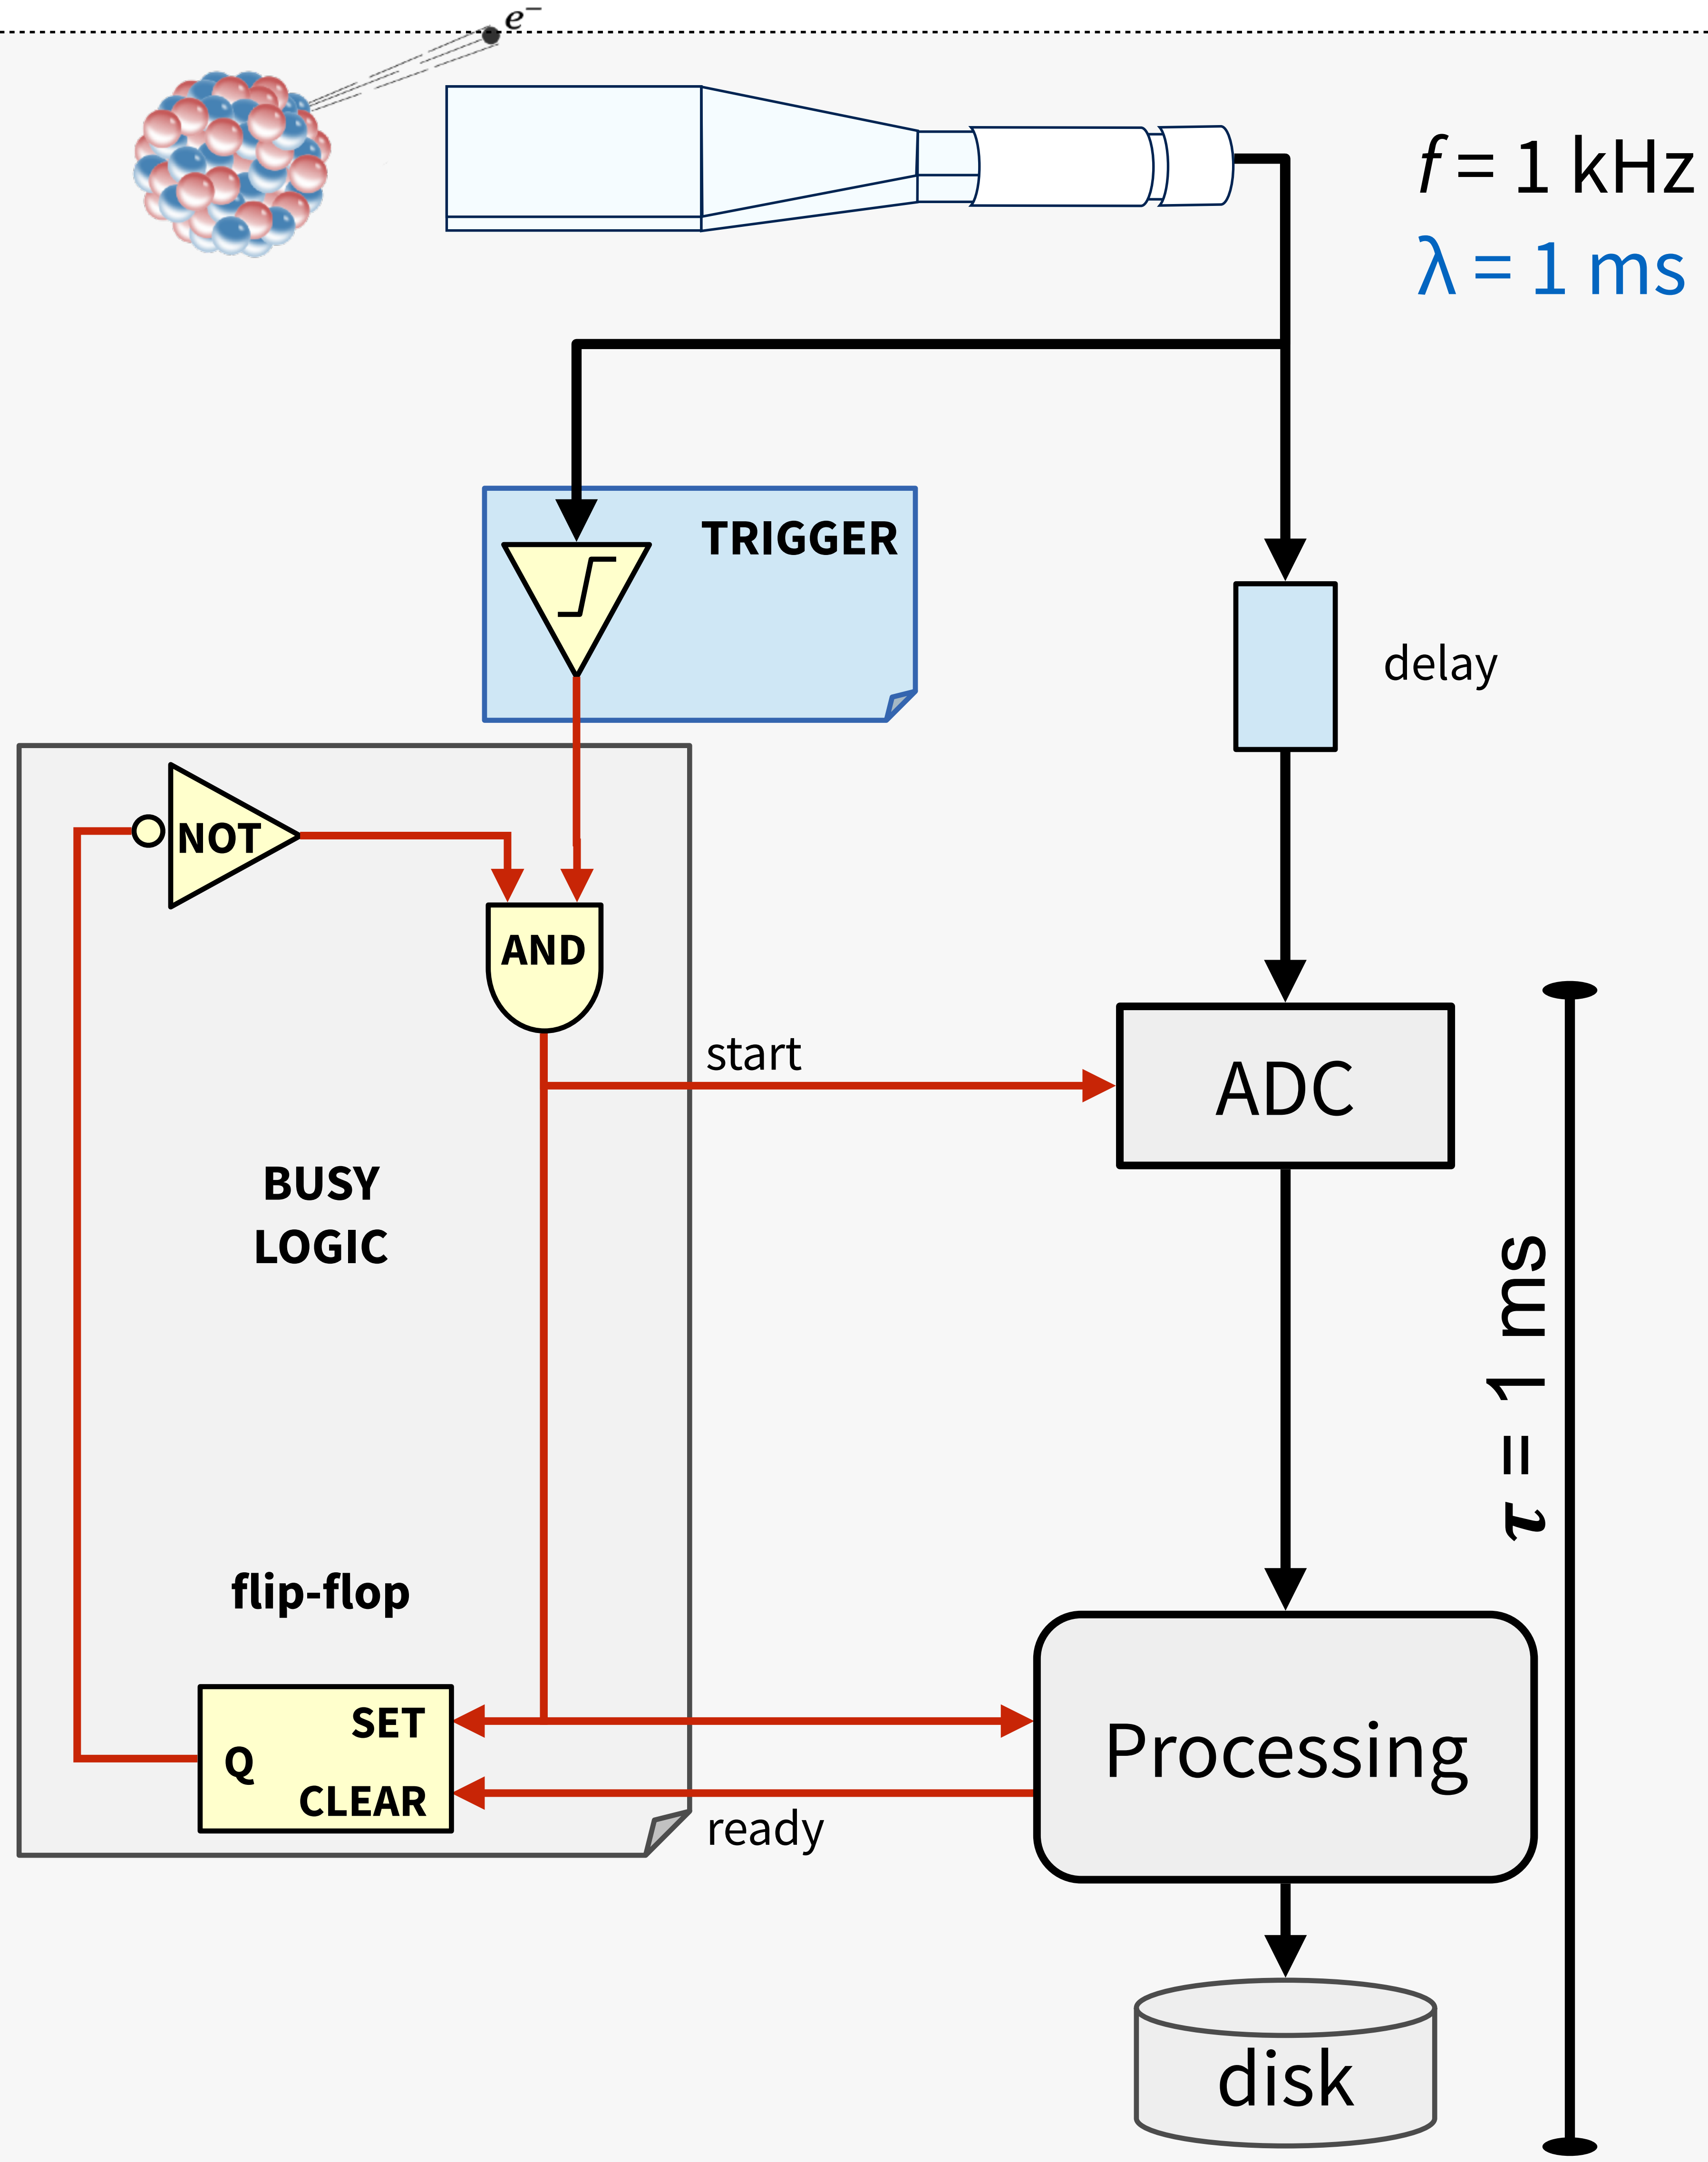
De-randomization

Input fluctuations can be absorbed and smoothed by a queue

- A FIFO can provide a ~steady and de-randomized output rate
- The effect of the queue depends on its depth

Busy is now defined by the buffer occupancy

- Processor pulls data from the buffer at fixed rate, separating the event receiving and data processing steps



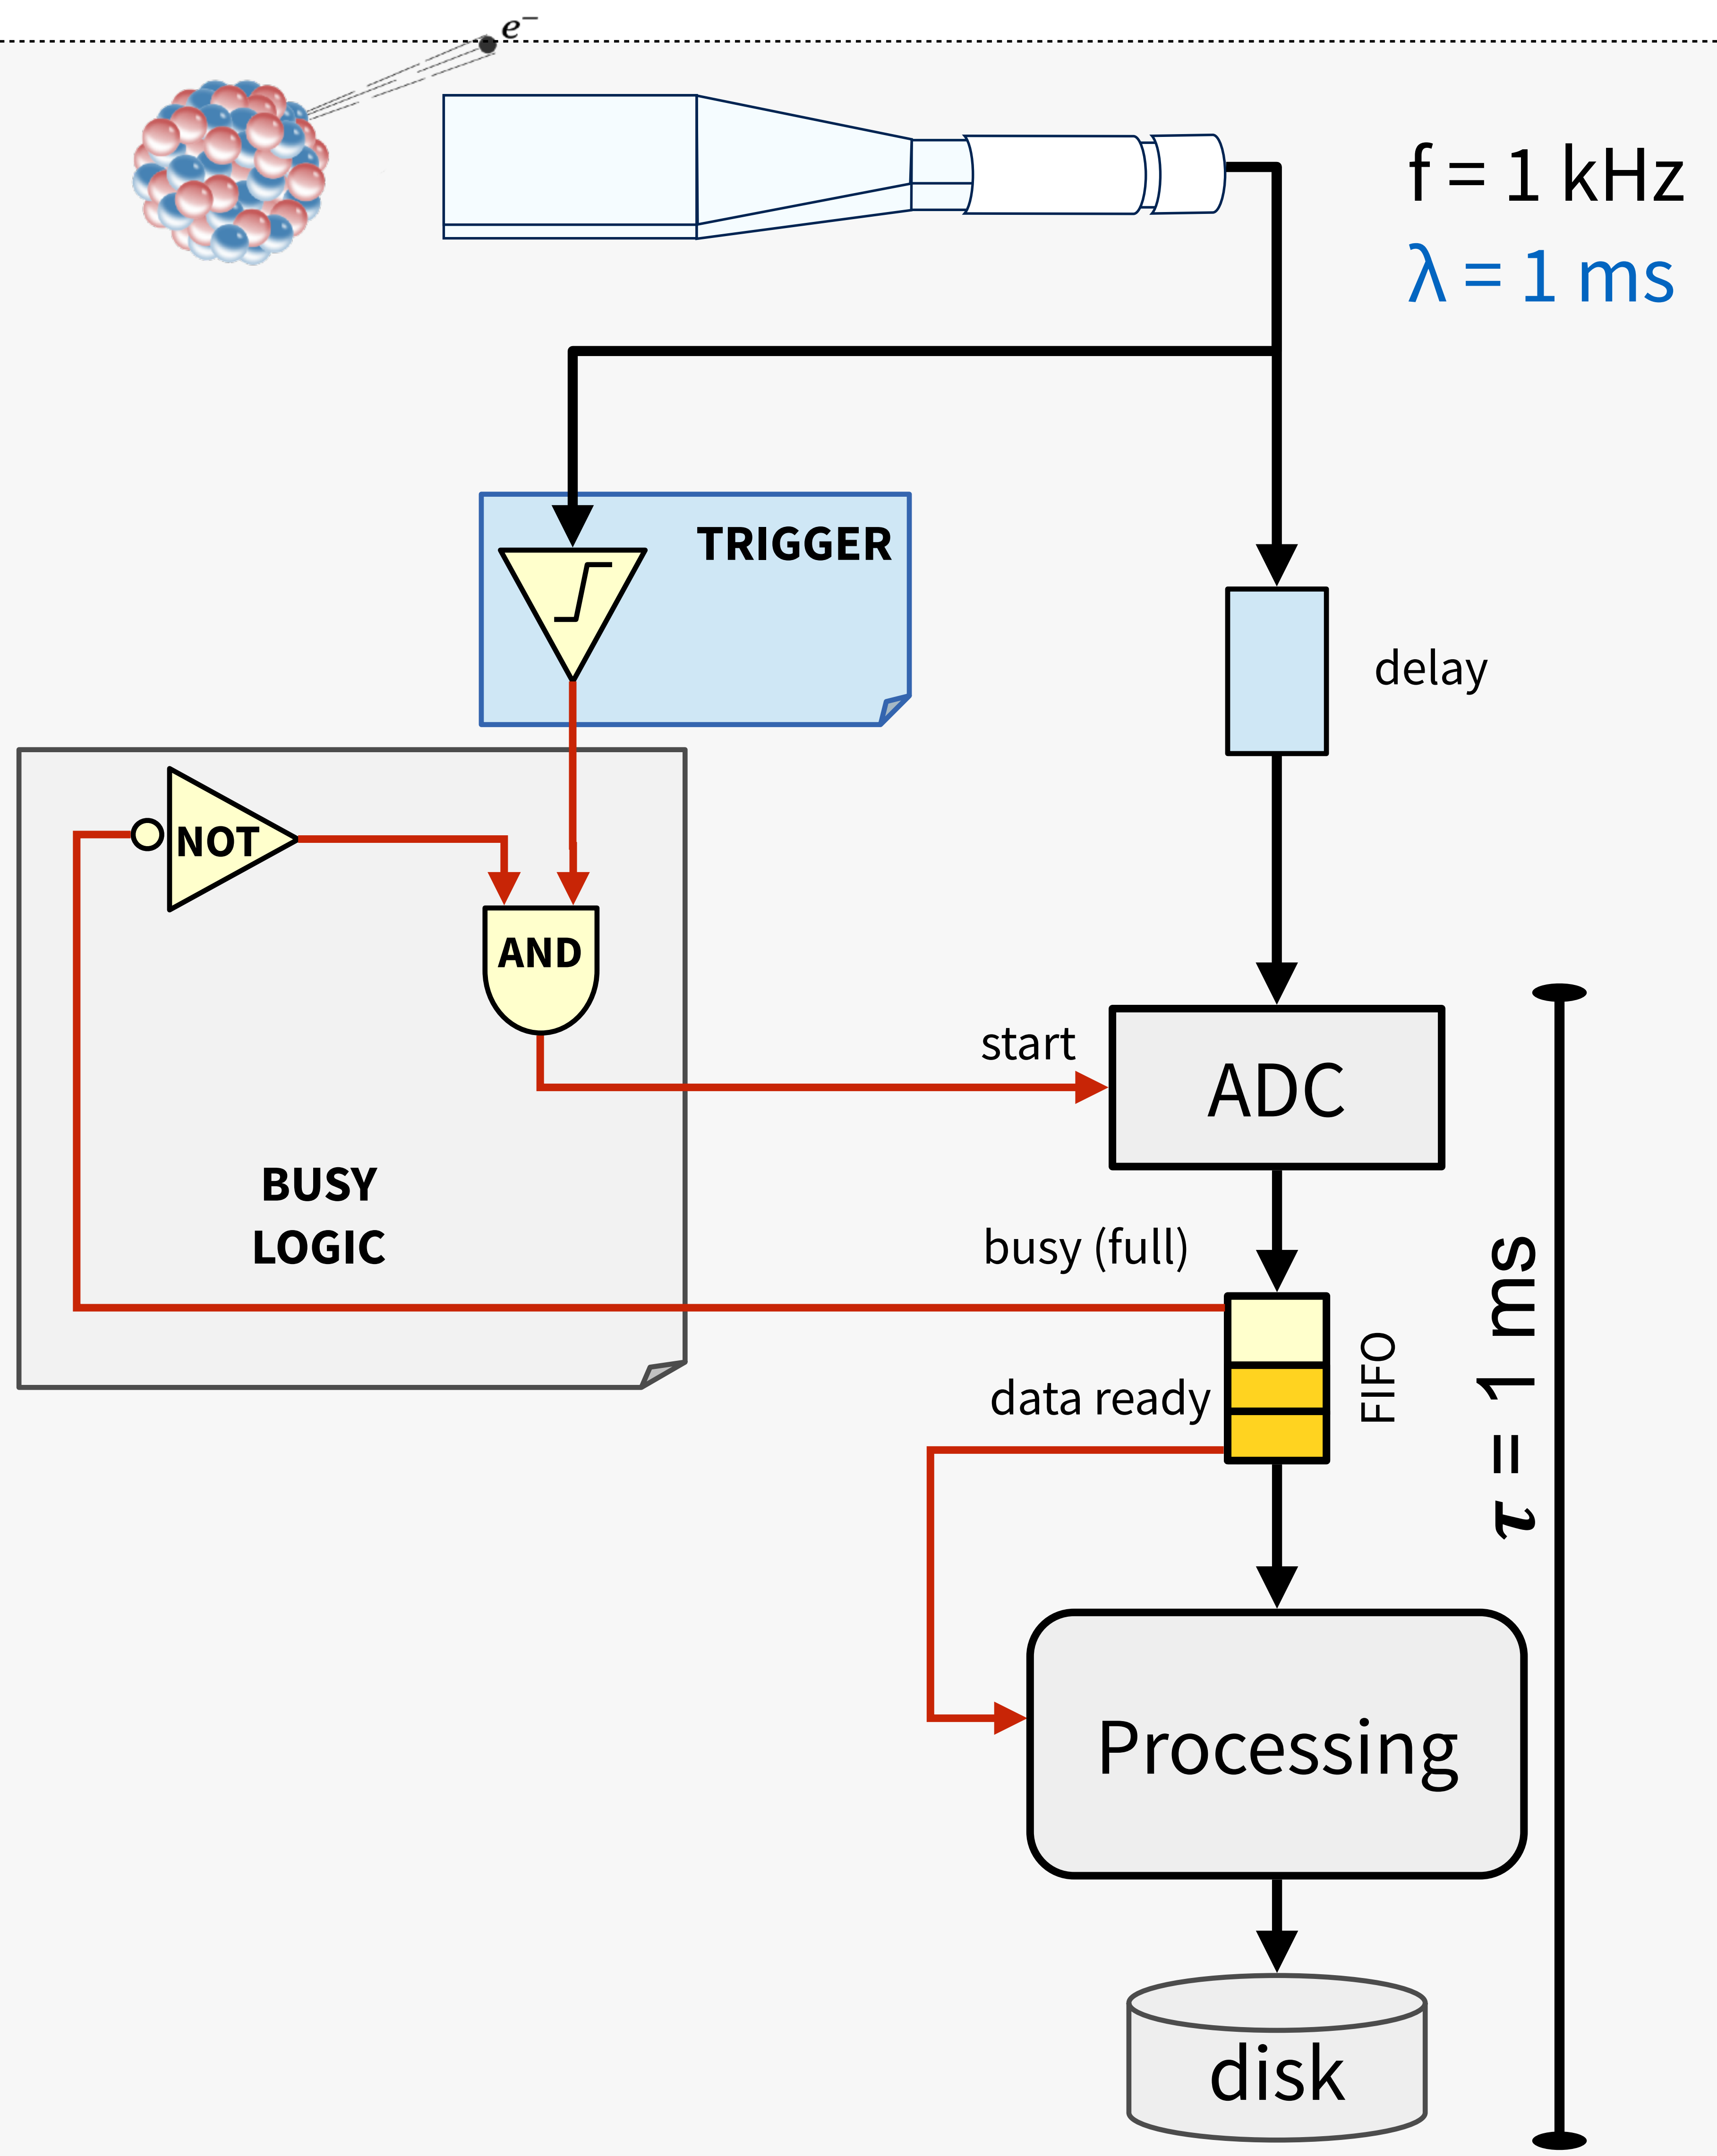
De-randomization

Input fluctuations can be absorbed and smoothed by a queue

- A FIFO can provide a ~steady and de-randomized output rate
- The effect of the queue depends on its depth

Busy is now defined by the buffer occupancy

- Processor pulls data from the buffer at fixed rate, separating the event receiving and data processing steps



De-randomization

The FIFO decouples the low latency front-end from the data processing

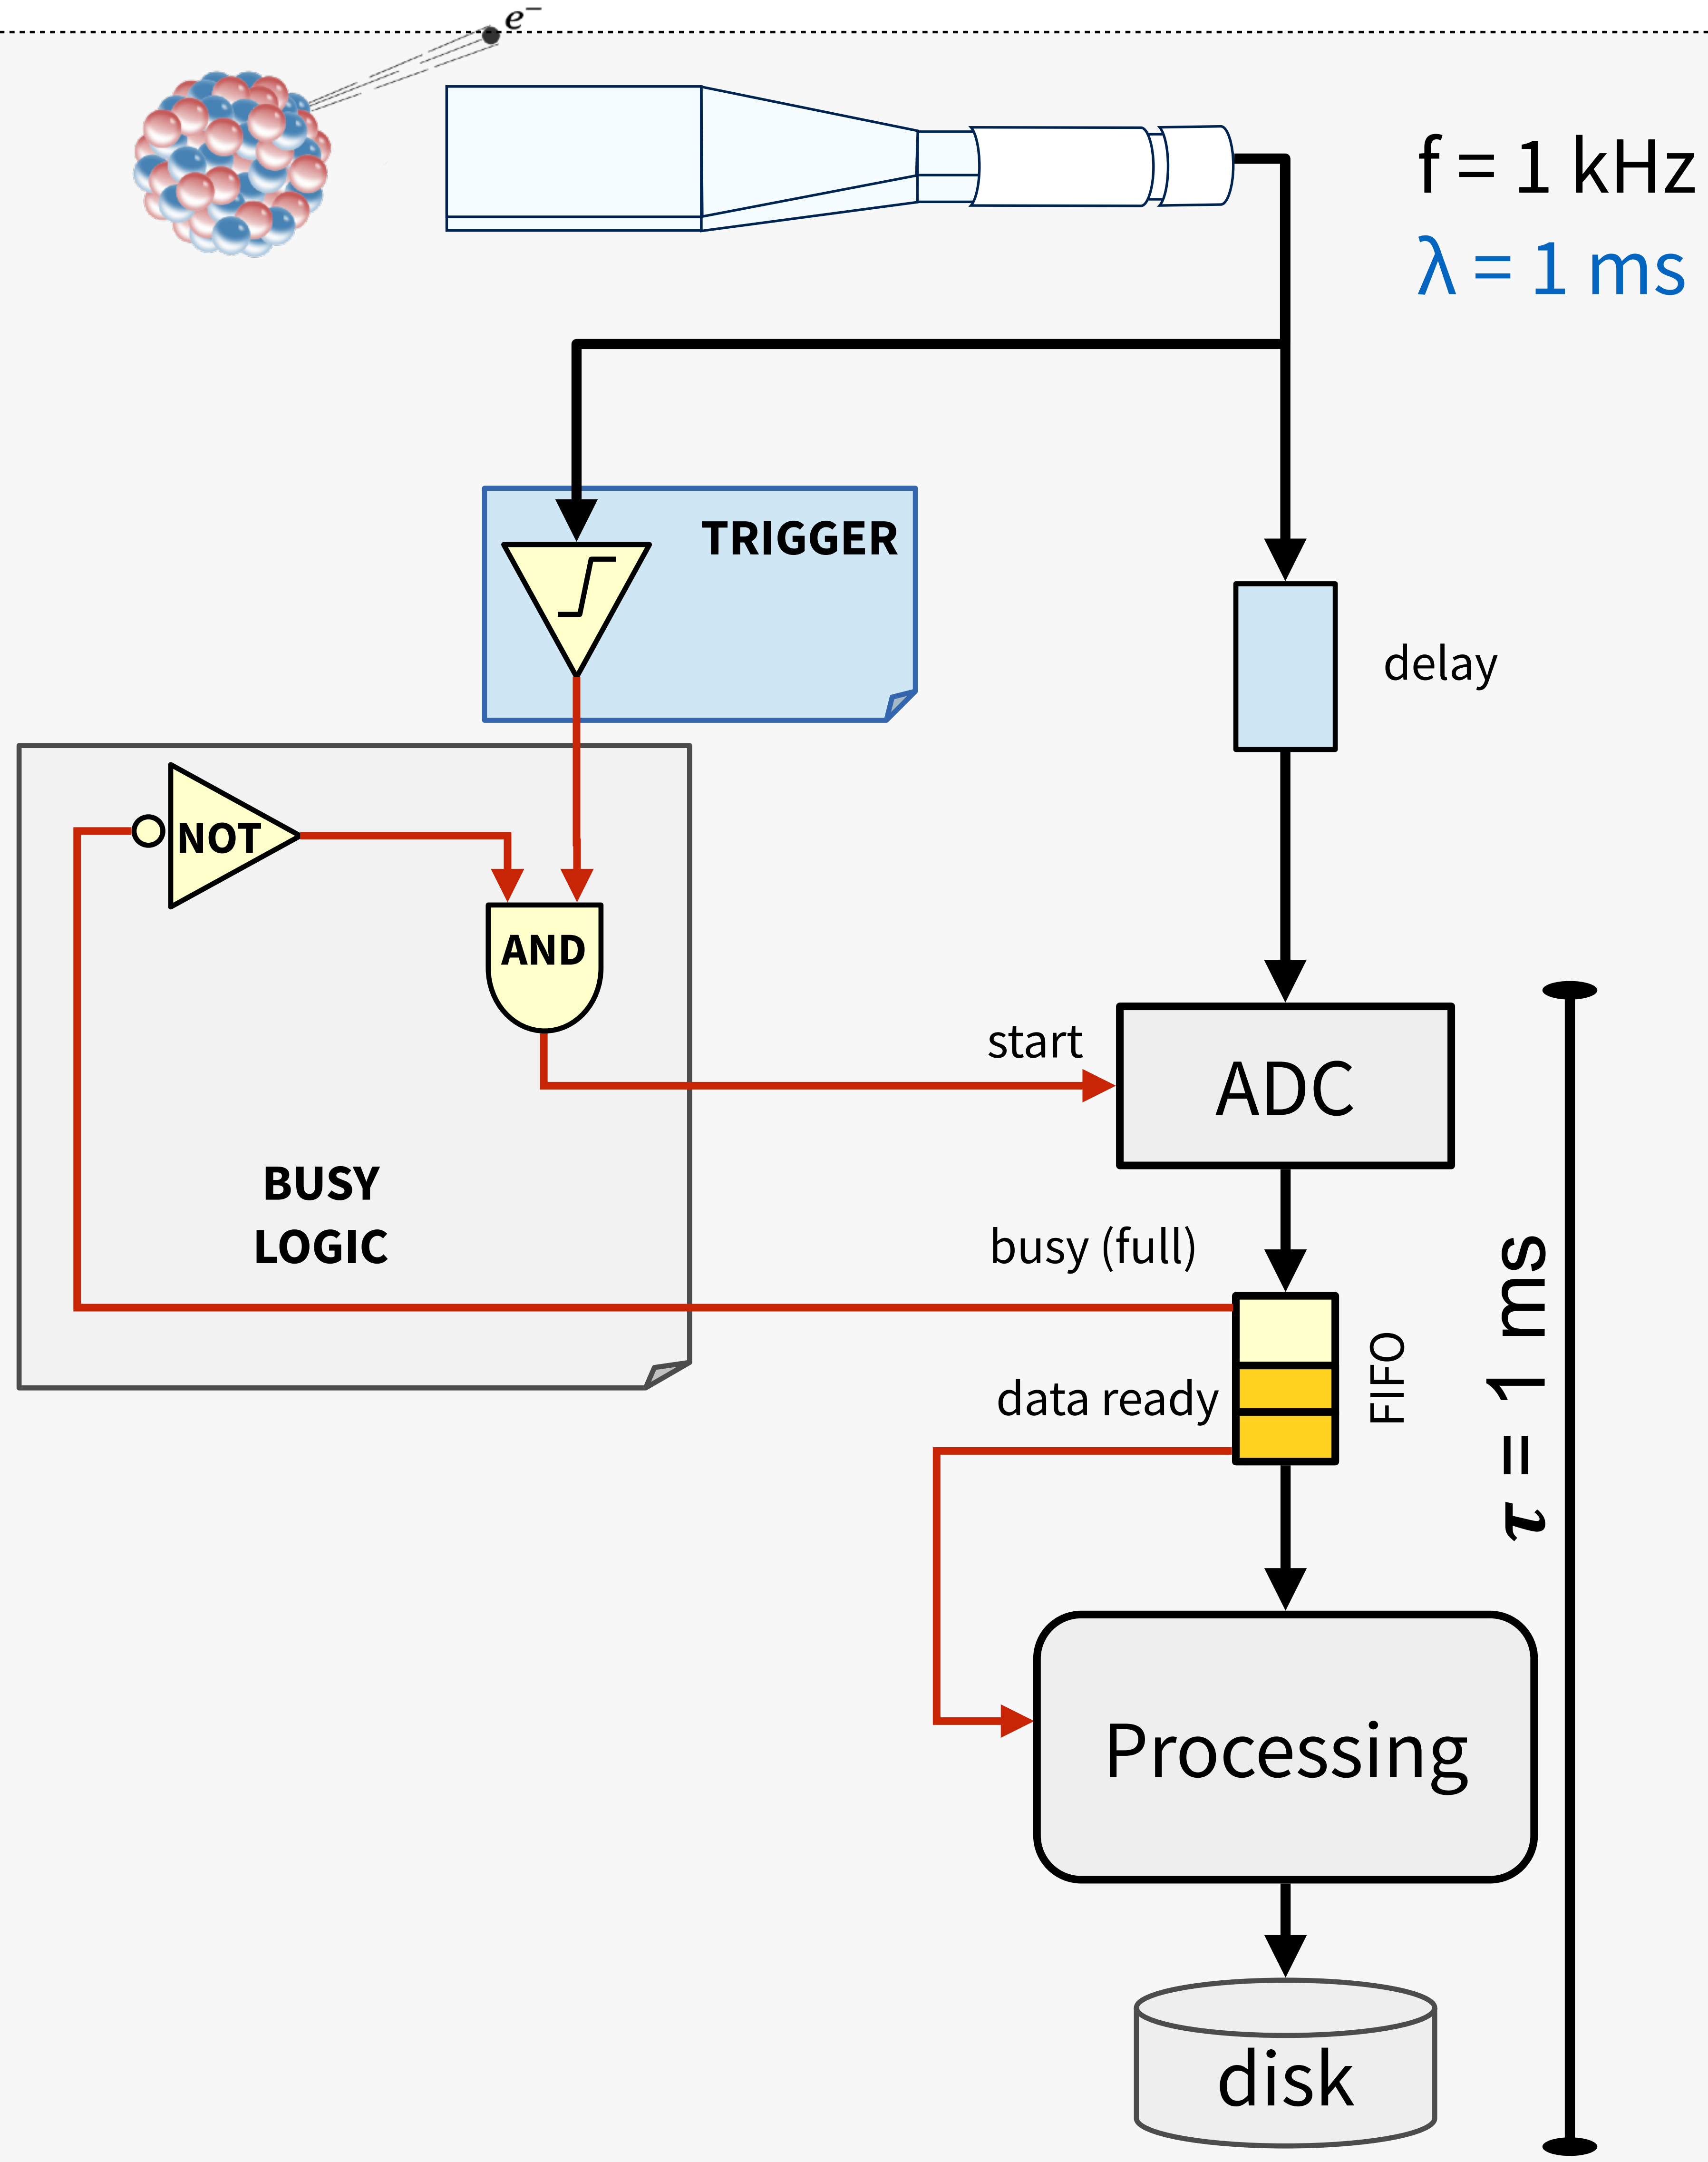
- Minimize the amount of "unnecessary" fast components

~100% efficiency w/ minimal deadtime achievable if

- ADC can operate at rate $\gg f$
- Data processing and storage operate at a rate $\sim f$

Could the delay be replaced with a "FIFO"?

- Analog pipelines, heavily used in LHC DAQs



De-randomization

The FIFO decouples the low latency front-end from the data processing

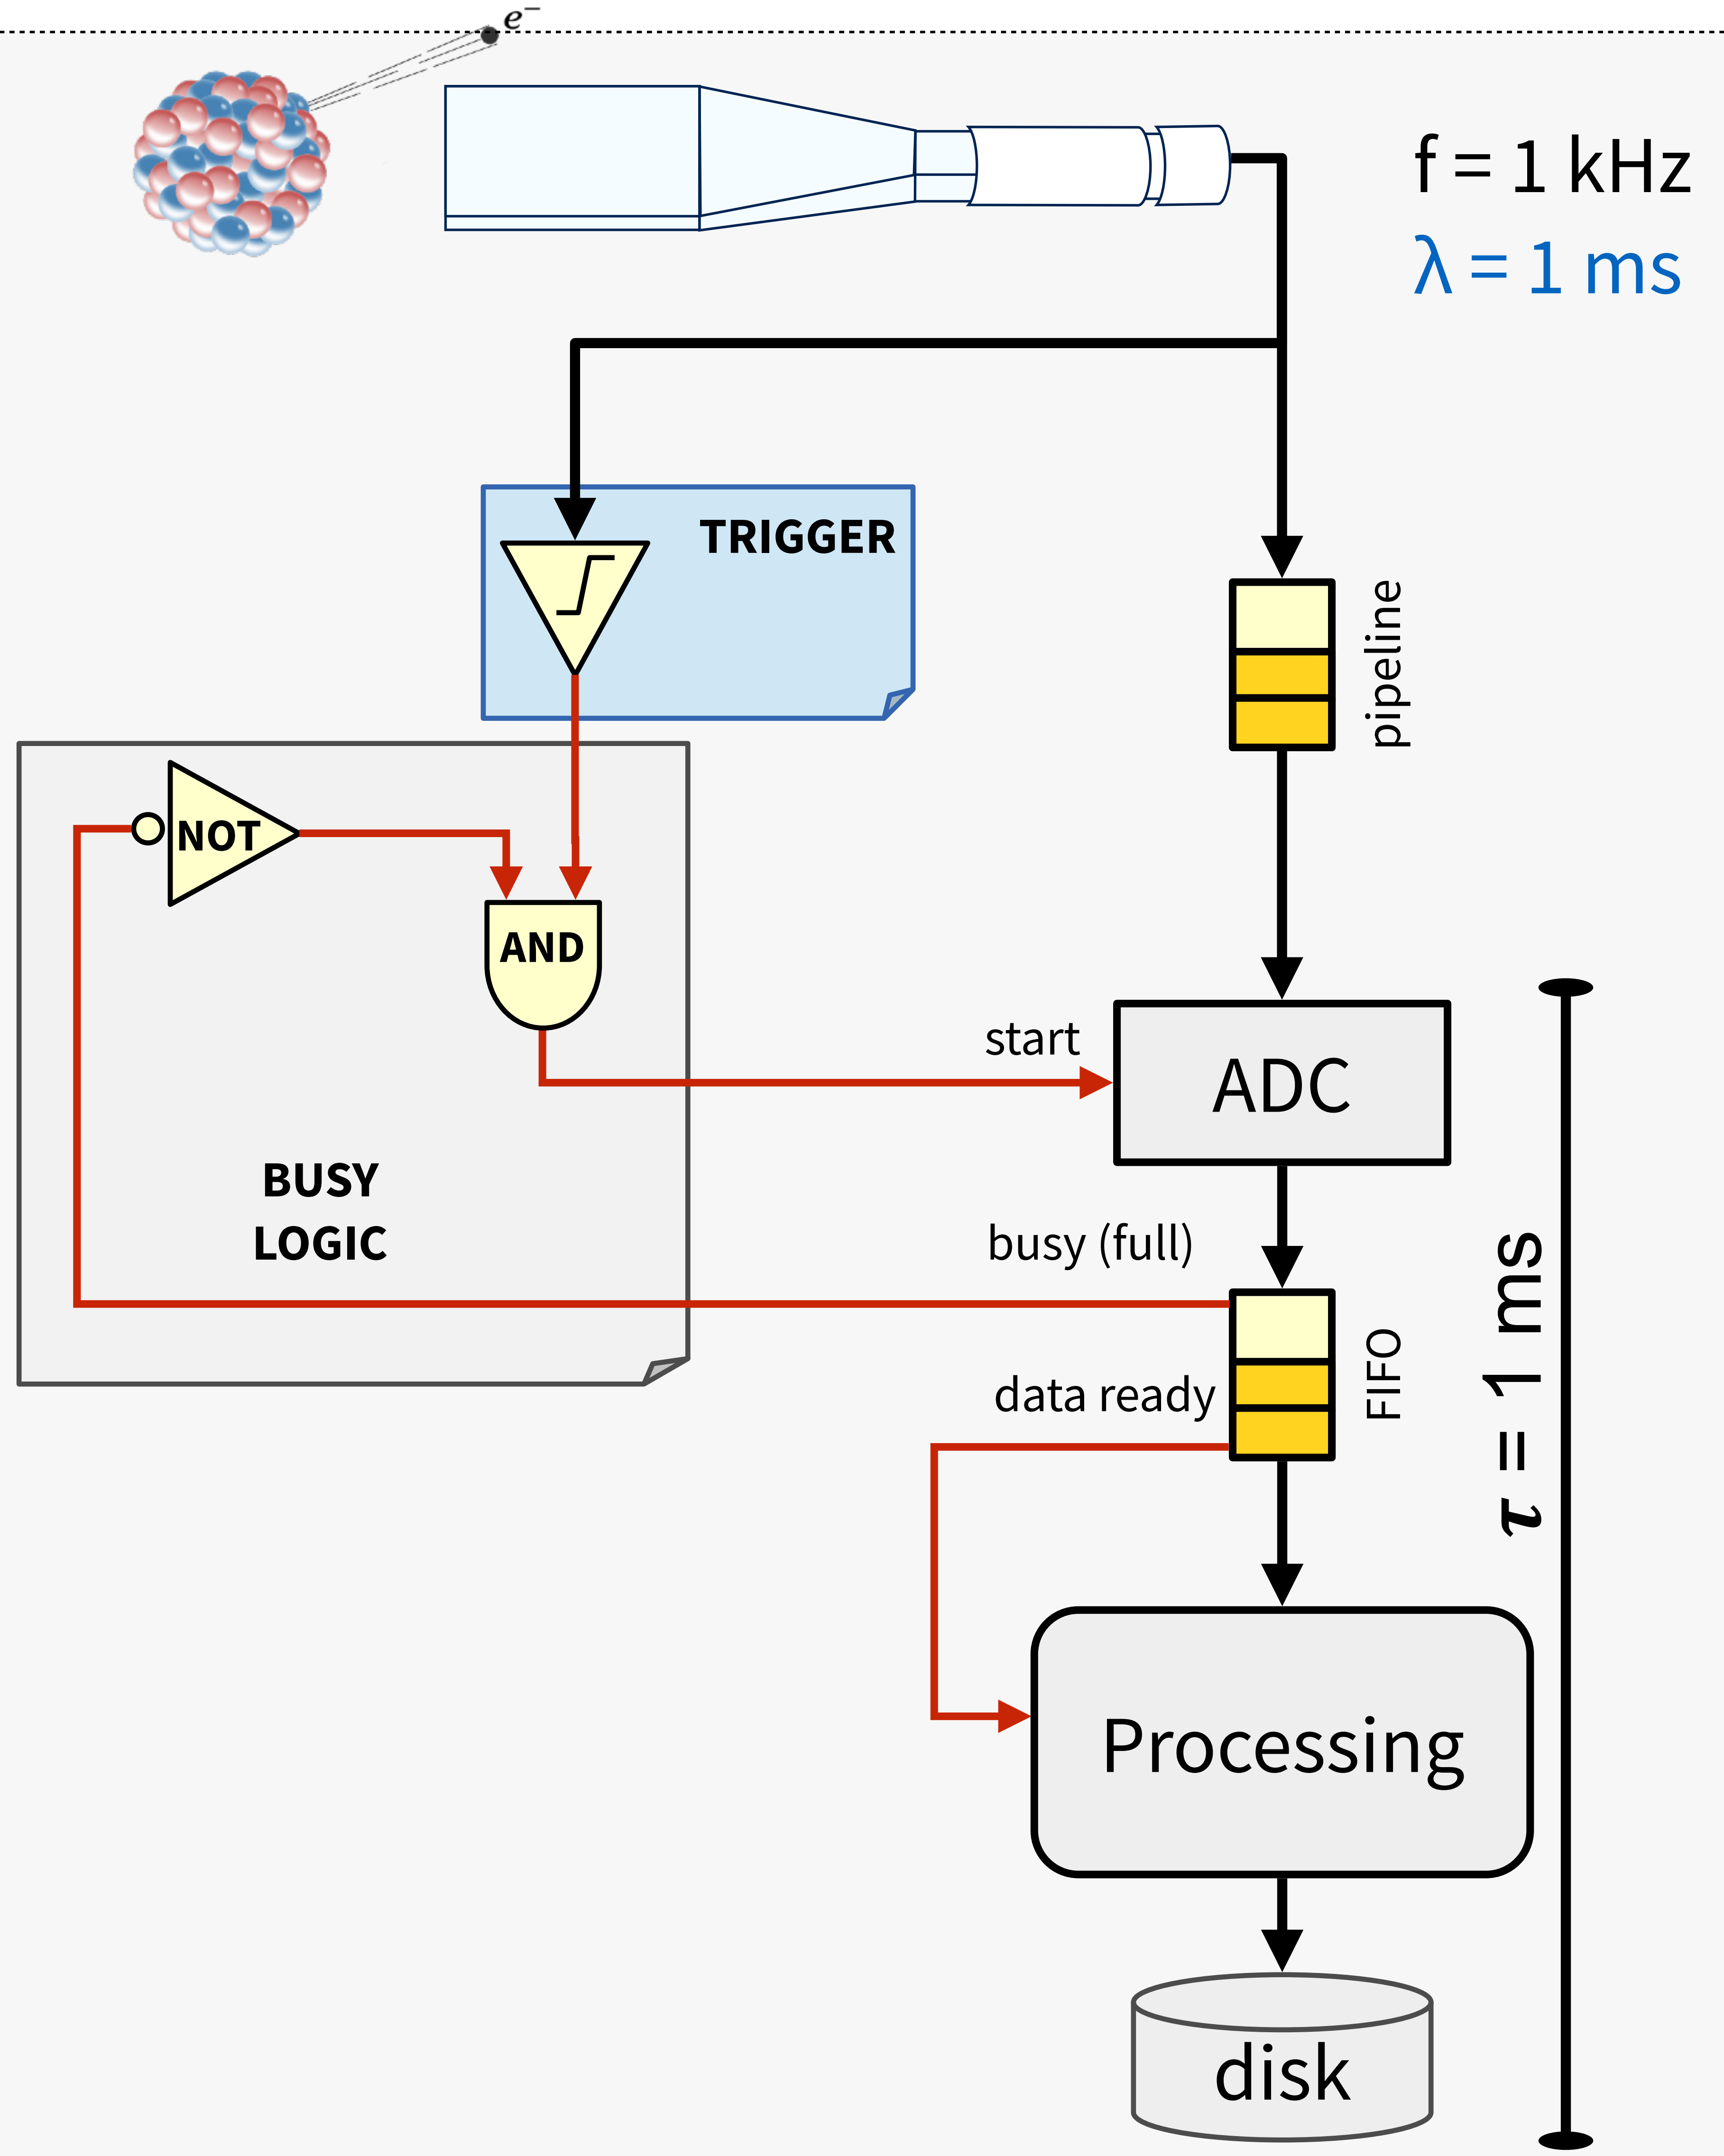
- Minimize the amount of "unnecessary" fast components

~100% efficiency w/ minimal deadtime achievable if

- ADC can operate at rate $\gg f$
- Data processing and storage operate at a rate $\sim f$

Could the delay be replaced with a "FIFO"?

- Analog pipelines, heavily used in LHC DAQs



Collider setup

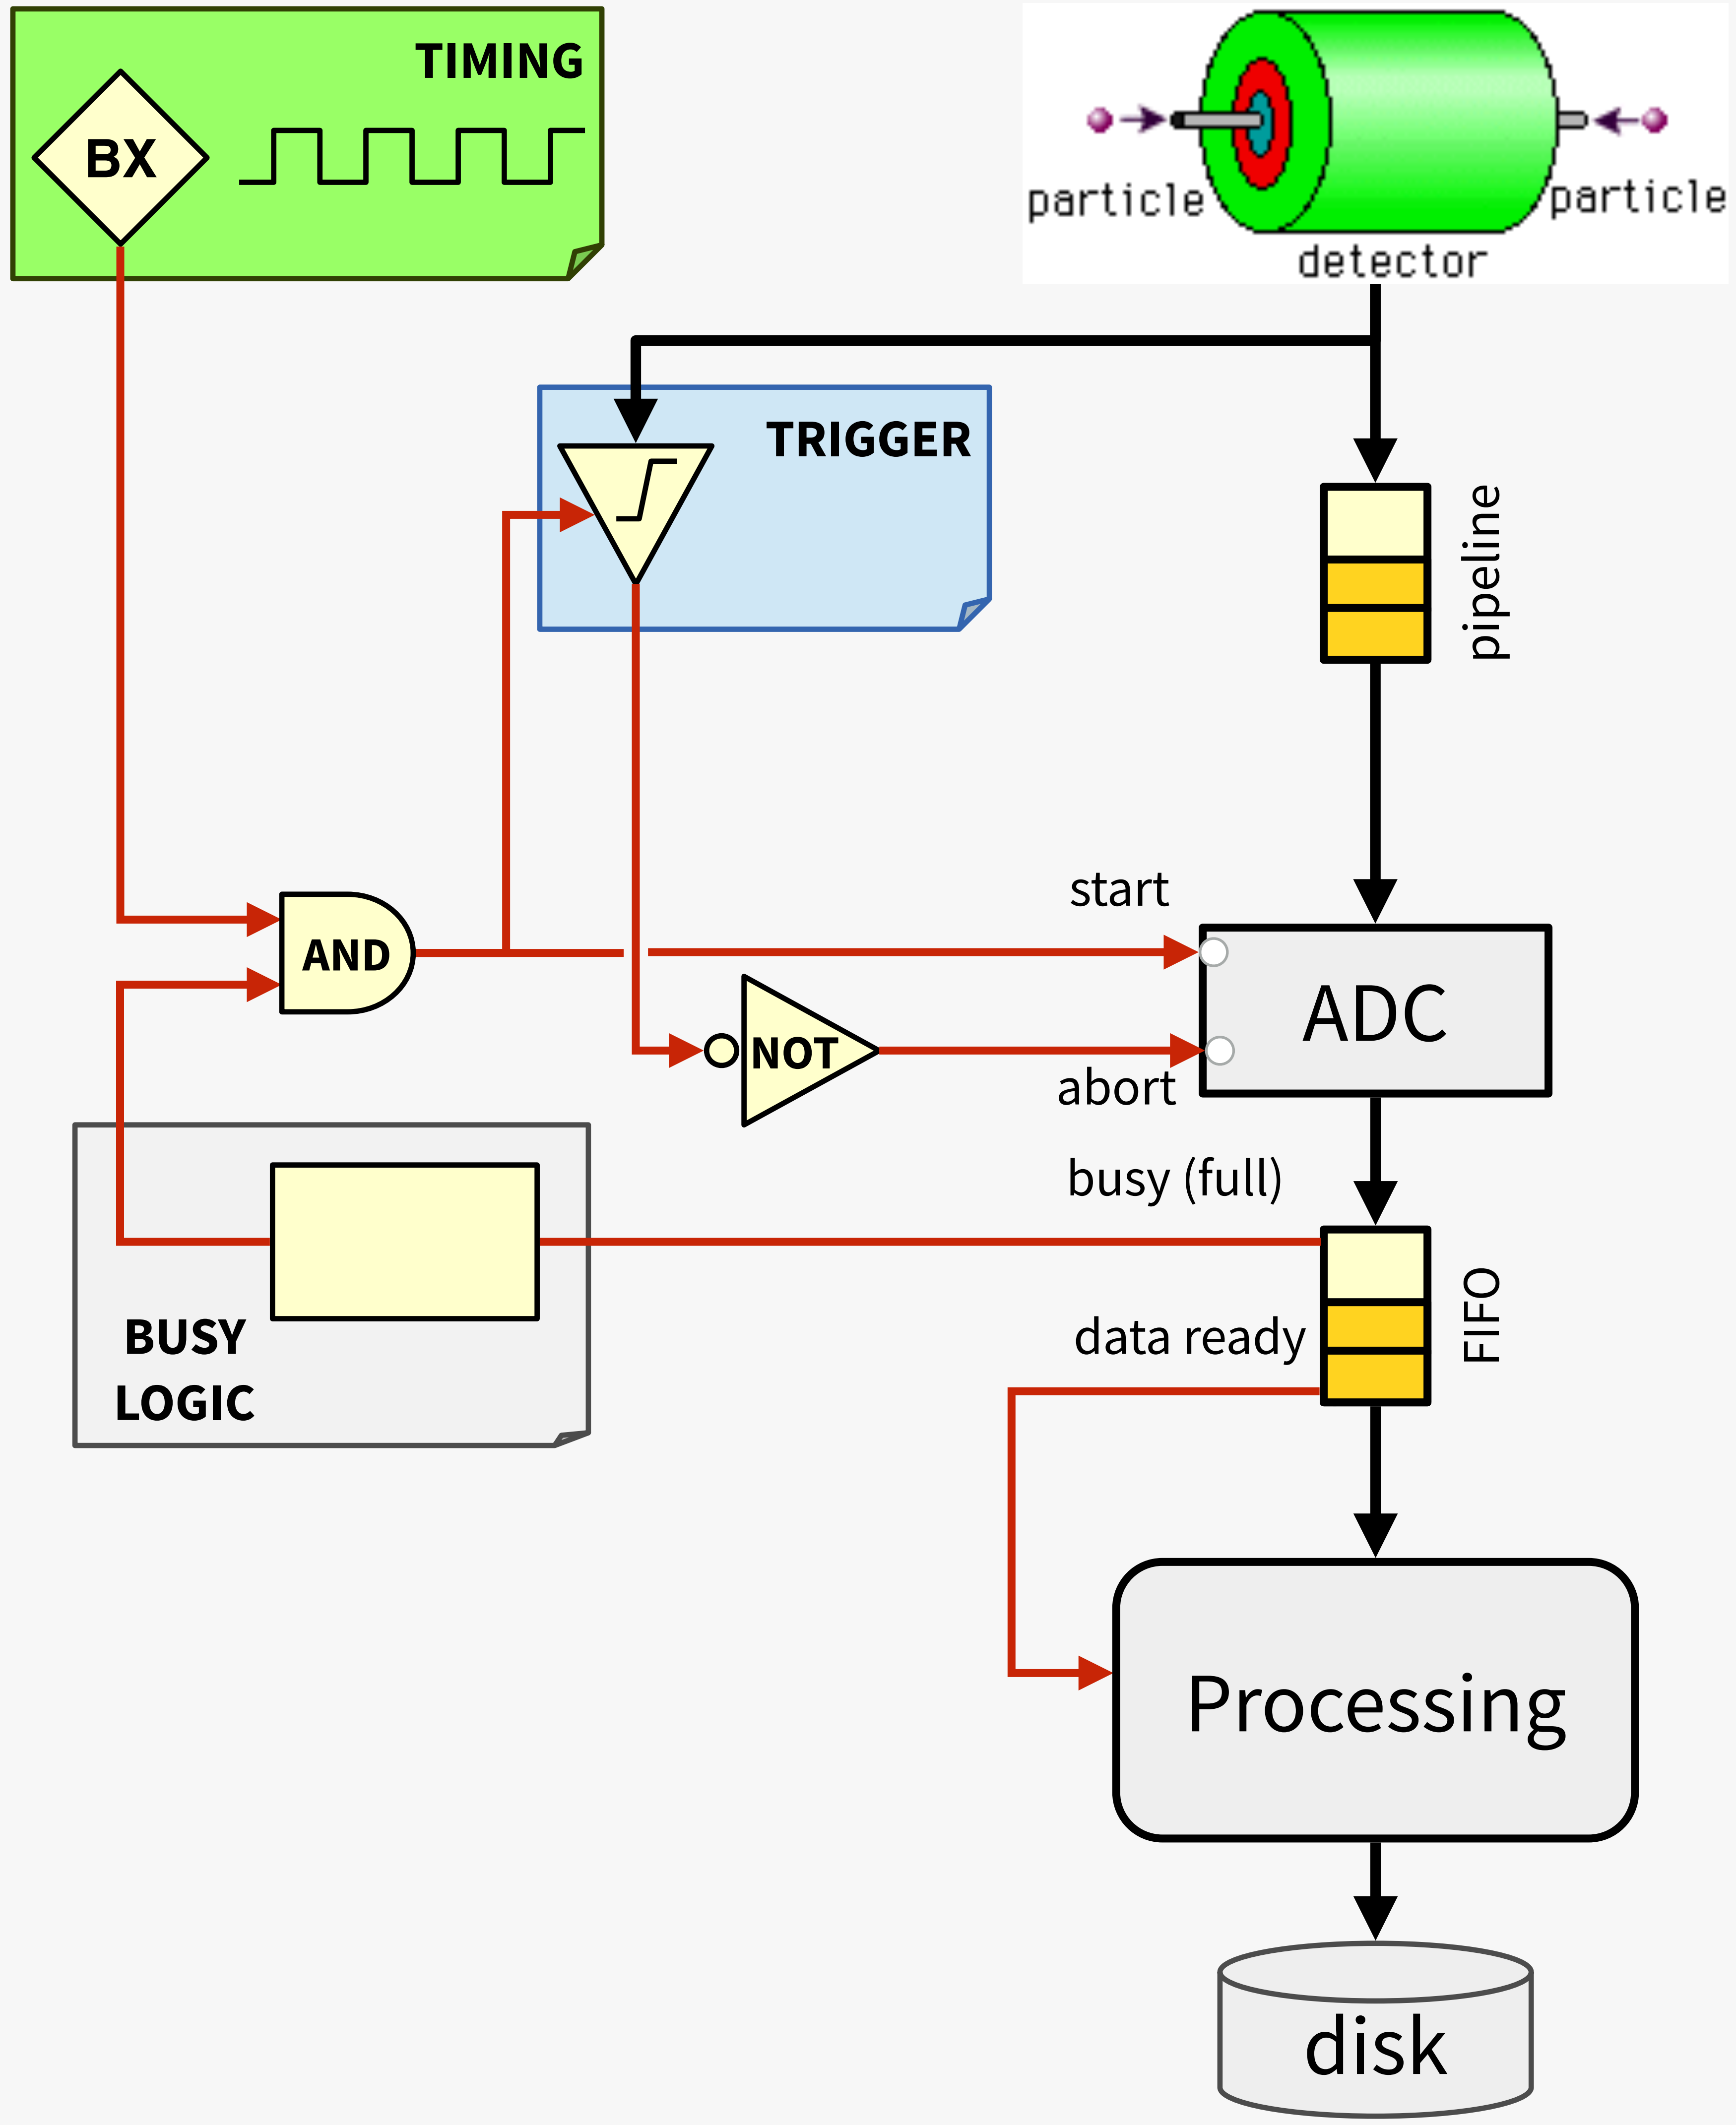
Do we need de-randomization buffers also in collider setups?

- Particle collisions are synchronous
- But the time distribution of triggers is random: interesting events are unpredictable

De-randomization still needed

More complex busy logic to protect buffers and detectors

- Eg: accept n events every m bunch crossings
- Eg: prevent some dangerous trigger patterns



Outline

1. Introduction

1.1. What is DAQ?

1.2. System architecture

2. Basic DAQ concepts

2.1. Digitization, Latency

2.2. Deadtime, Busy, Backpressure

2.3. De-randomization

3. Scaling up

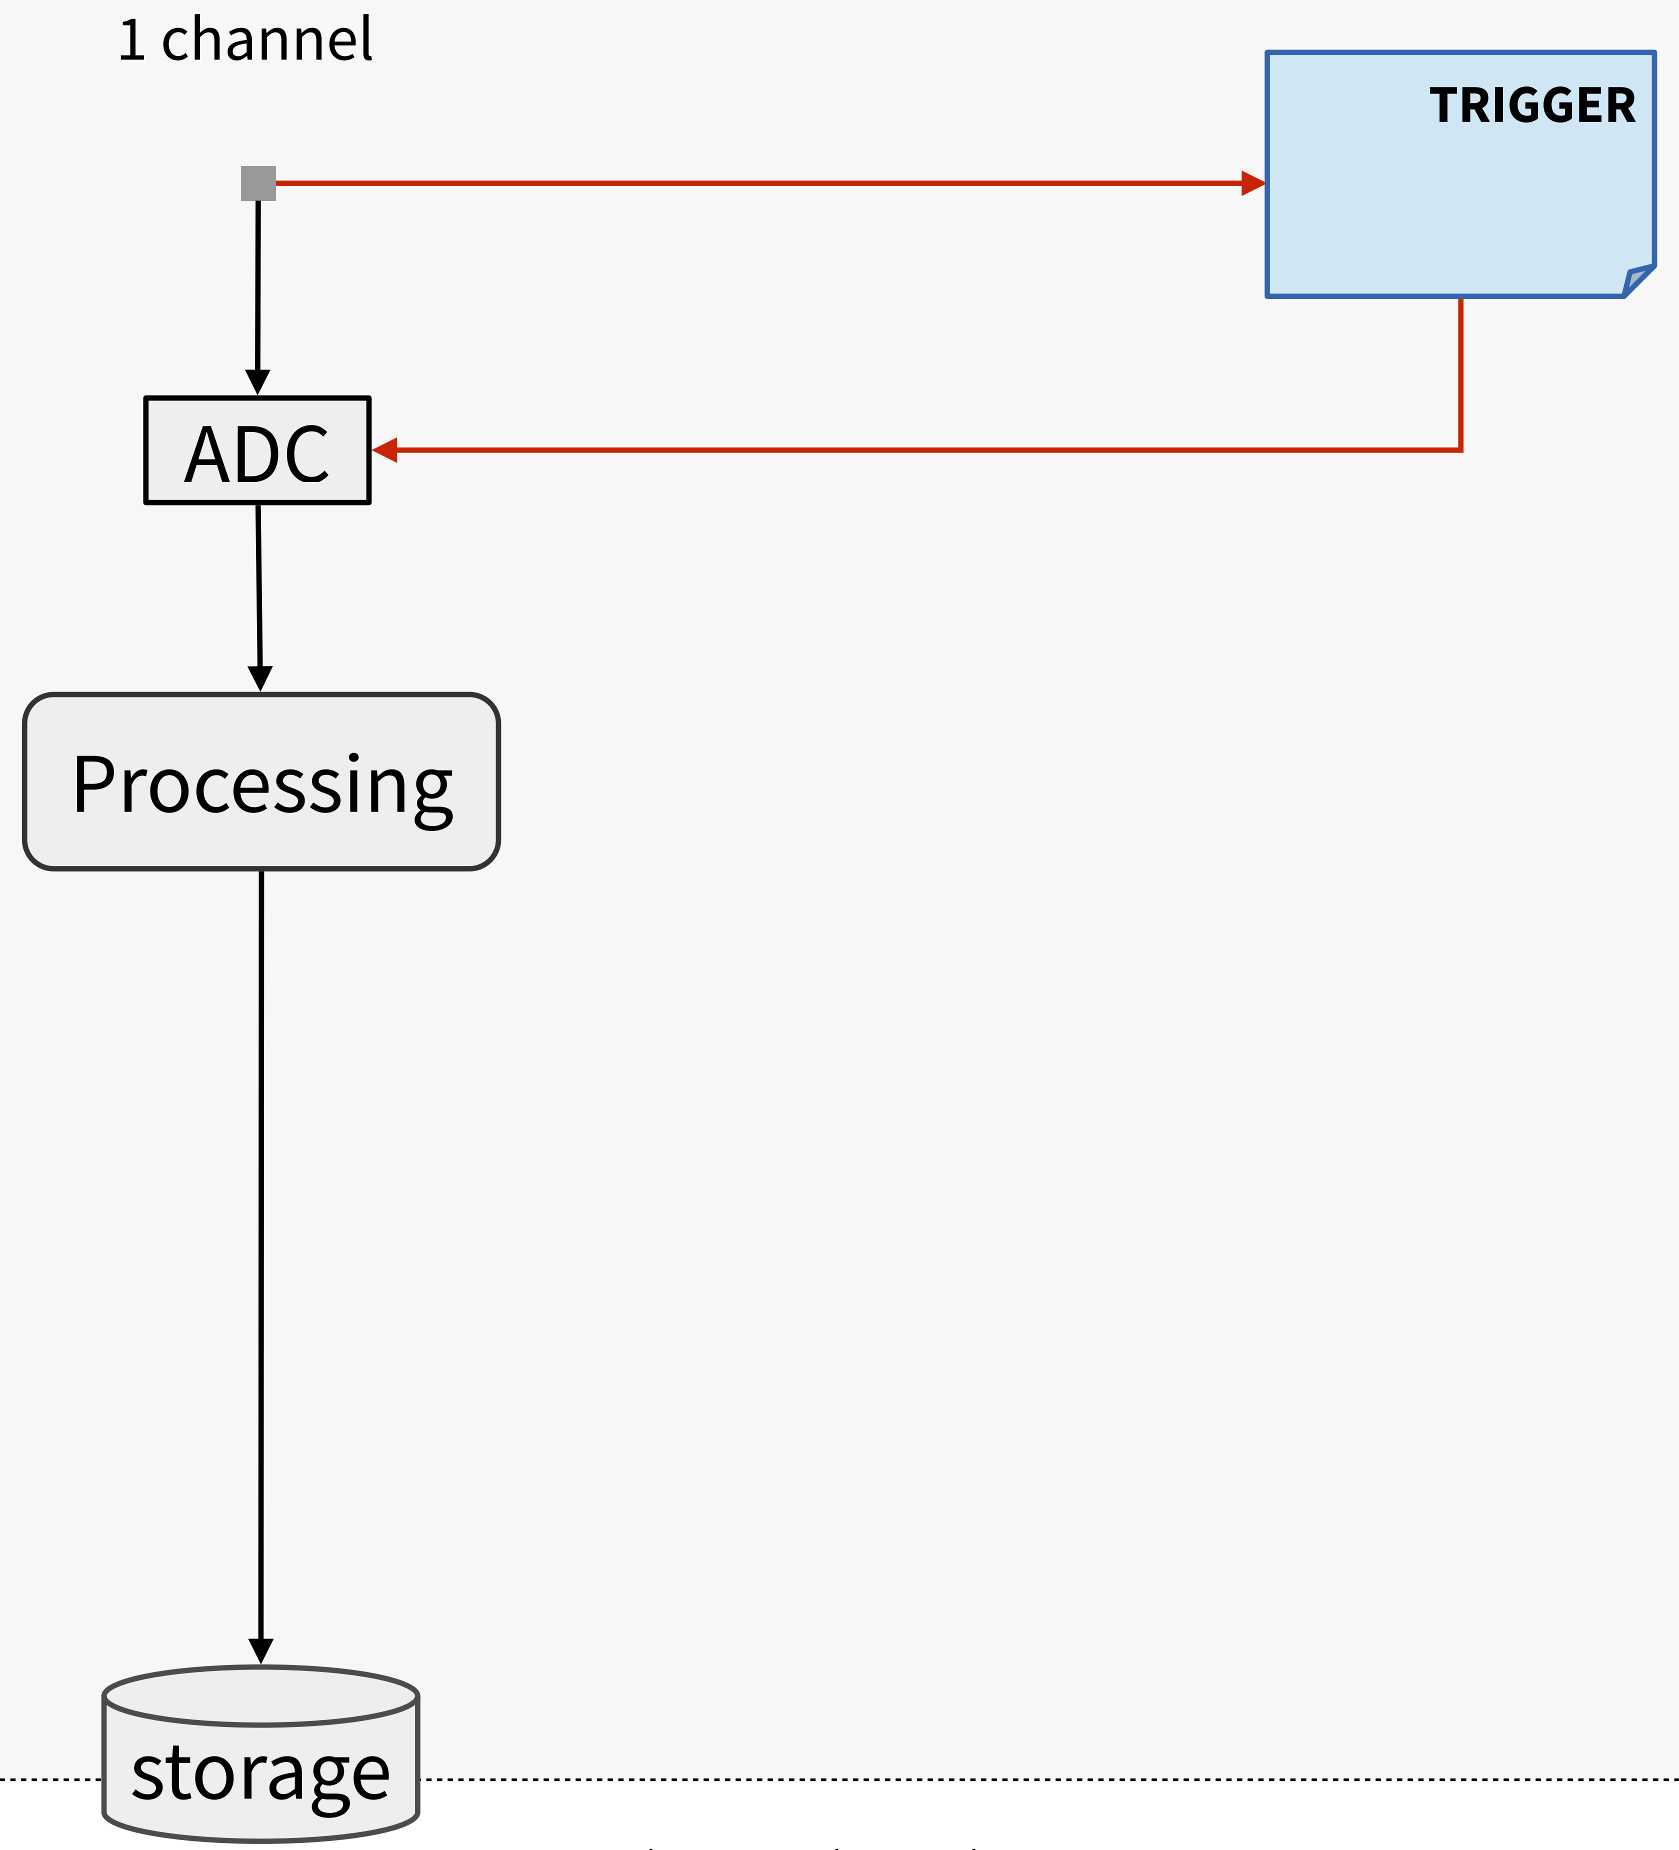
3.1. Readout and Event Building

3.2. Buses vs Network

4. DAQ Challenges at the LHC

Adding more channels

Adding more channels requires a hierarchical structure committed to the data handling and conveyance



Front-End | data digitization, data **buffering**

Readout | data extraction, data formatting, data **buffering**

Event Building | event assembly, event **buffering**

Event Filtering | event rejection, event **buffering**

Event Logging | file storage, file **buffering**

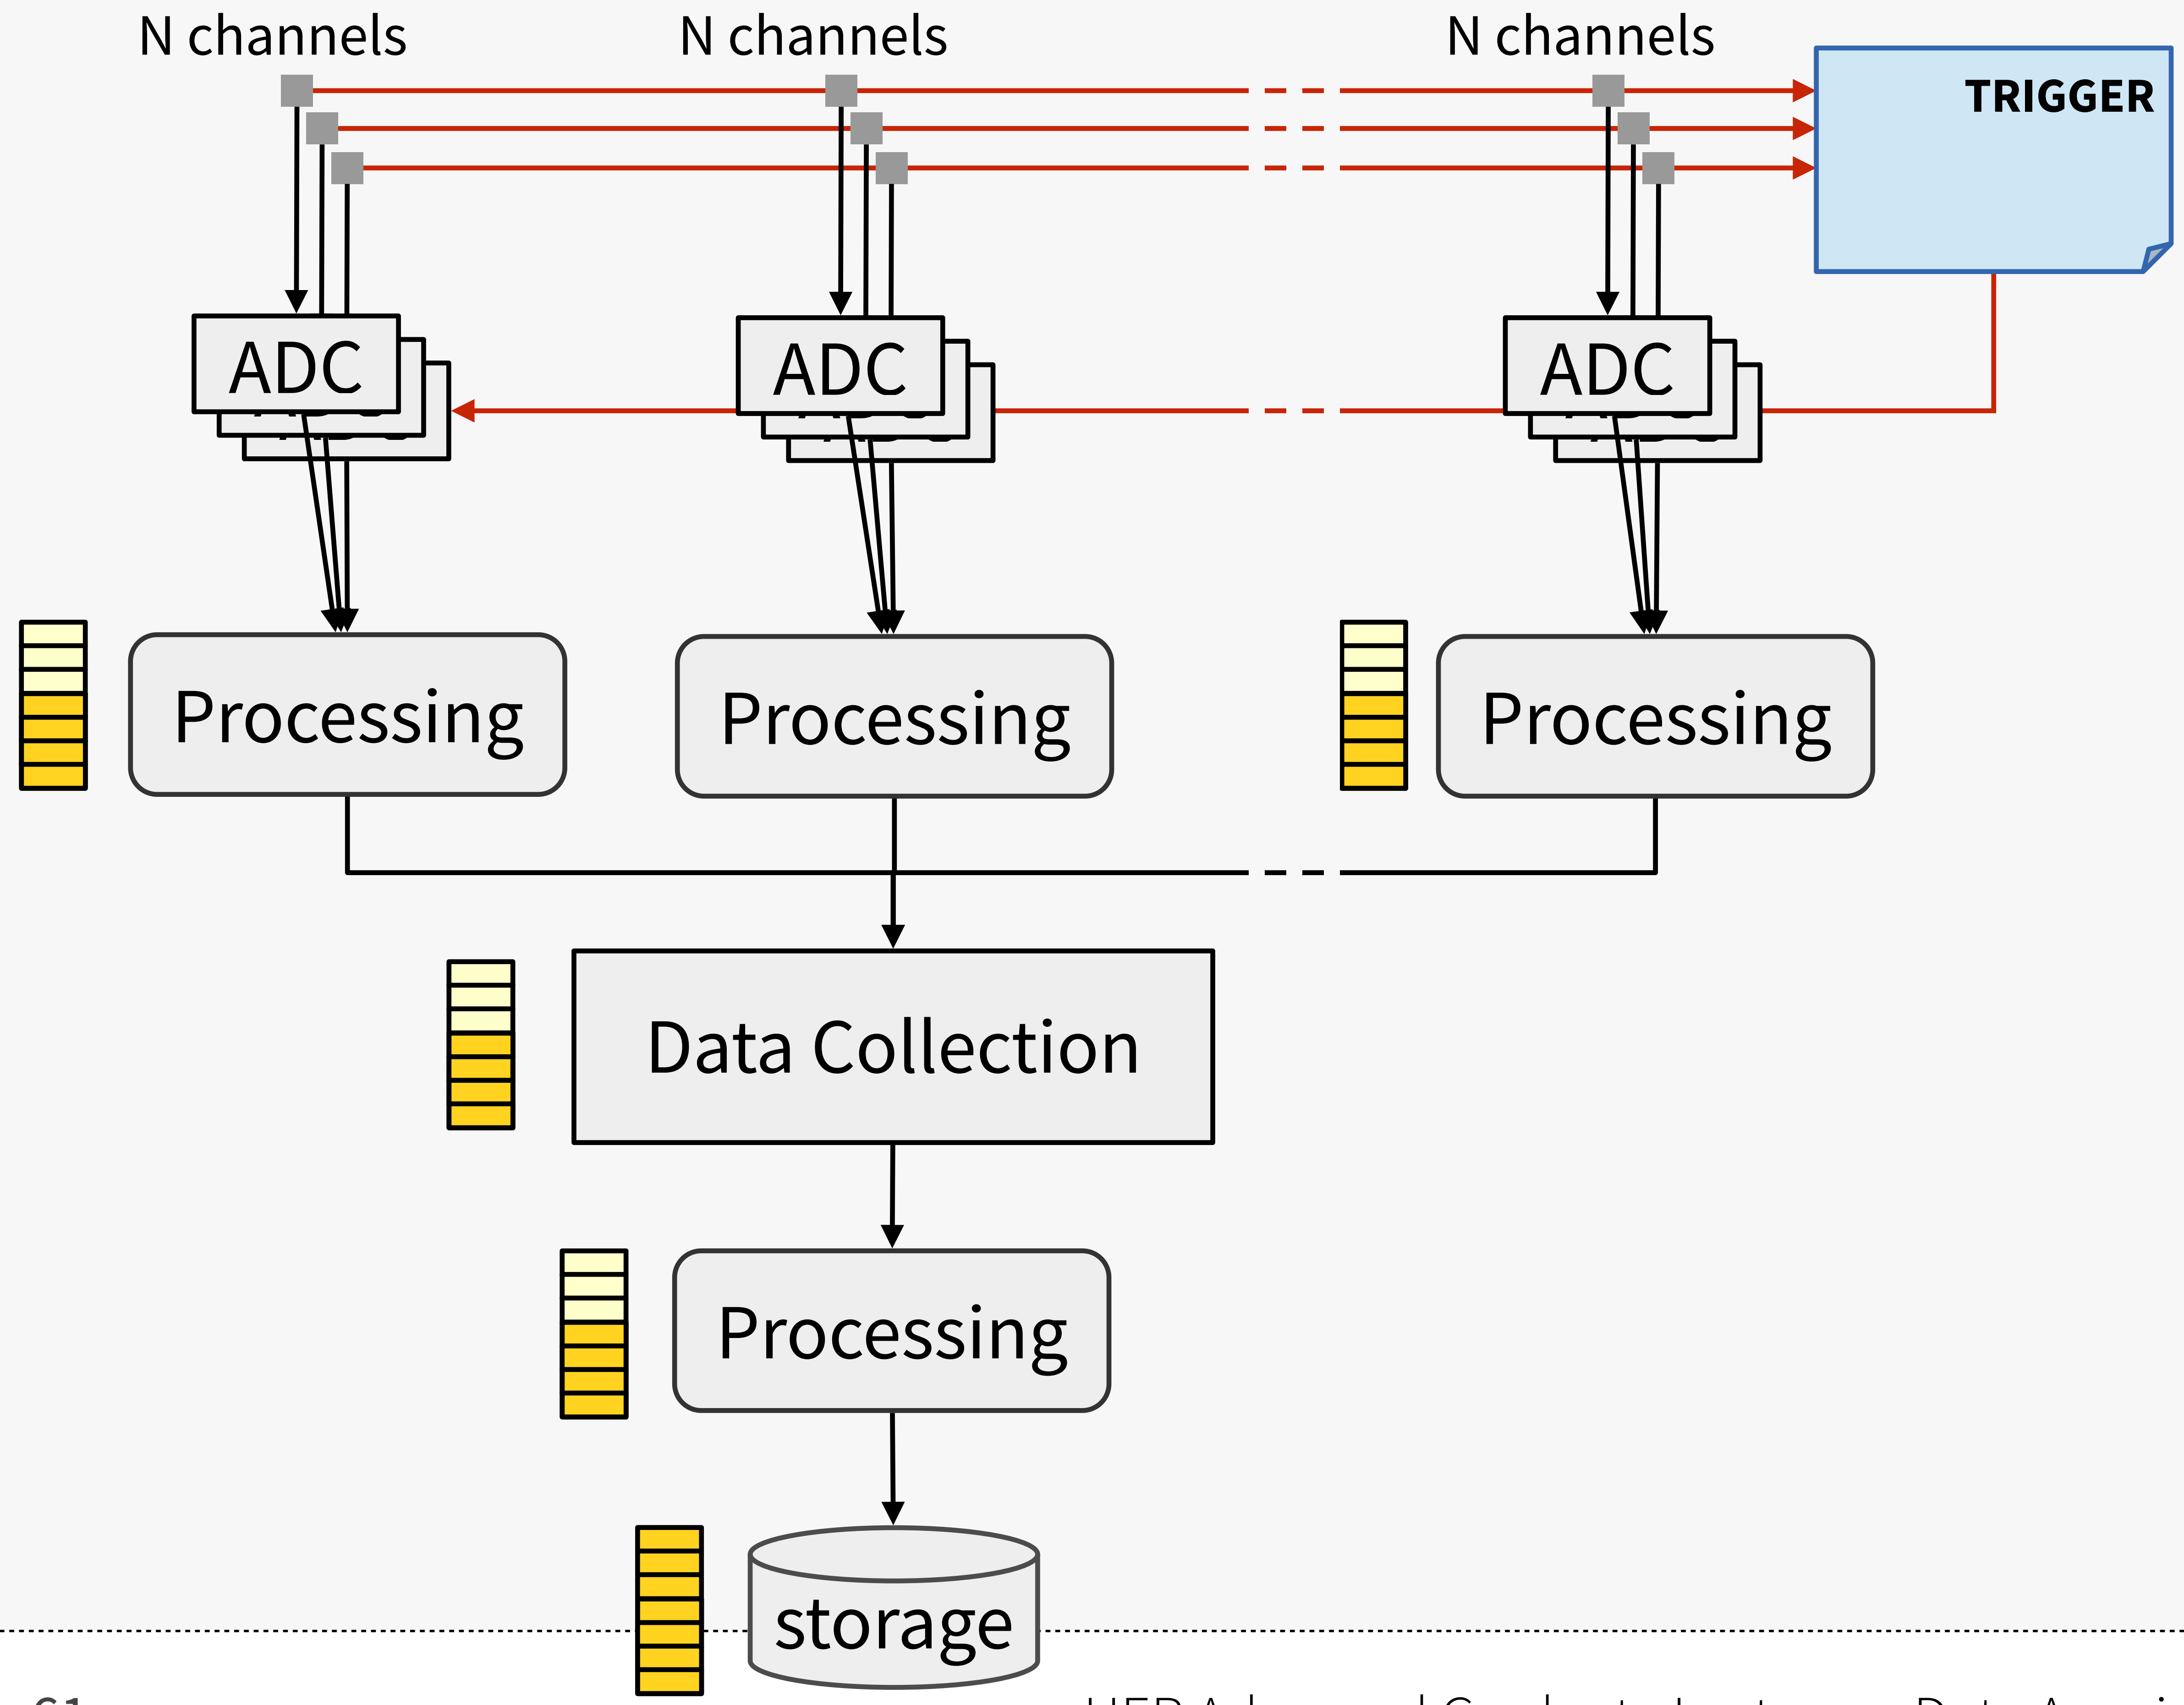
Backpressure

If a system/buffer gets saturated

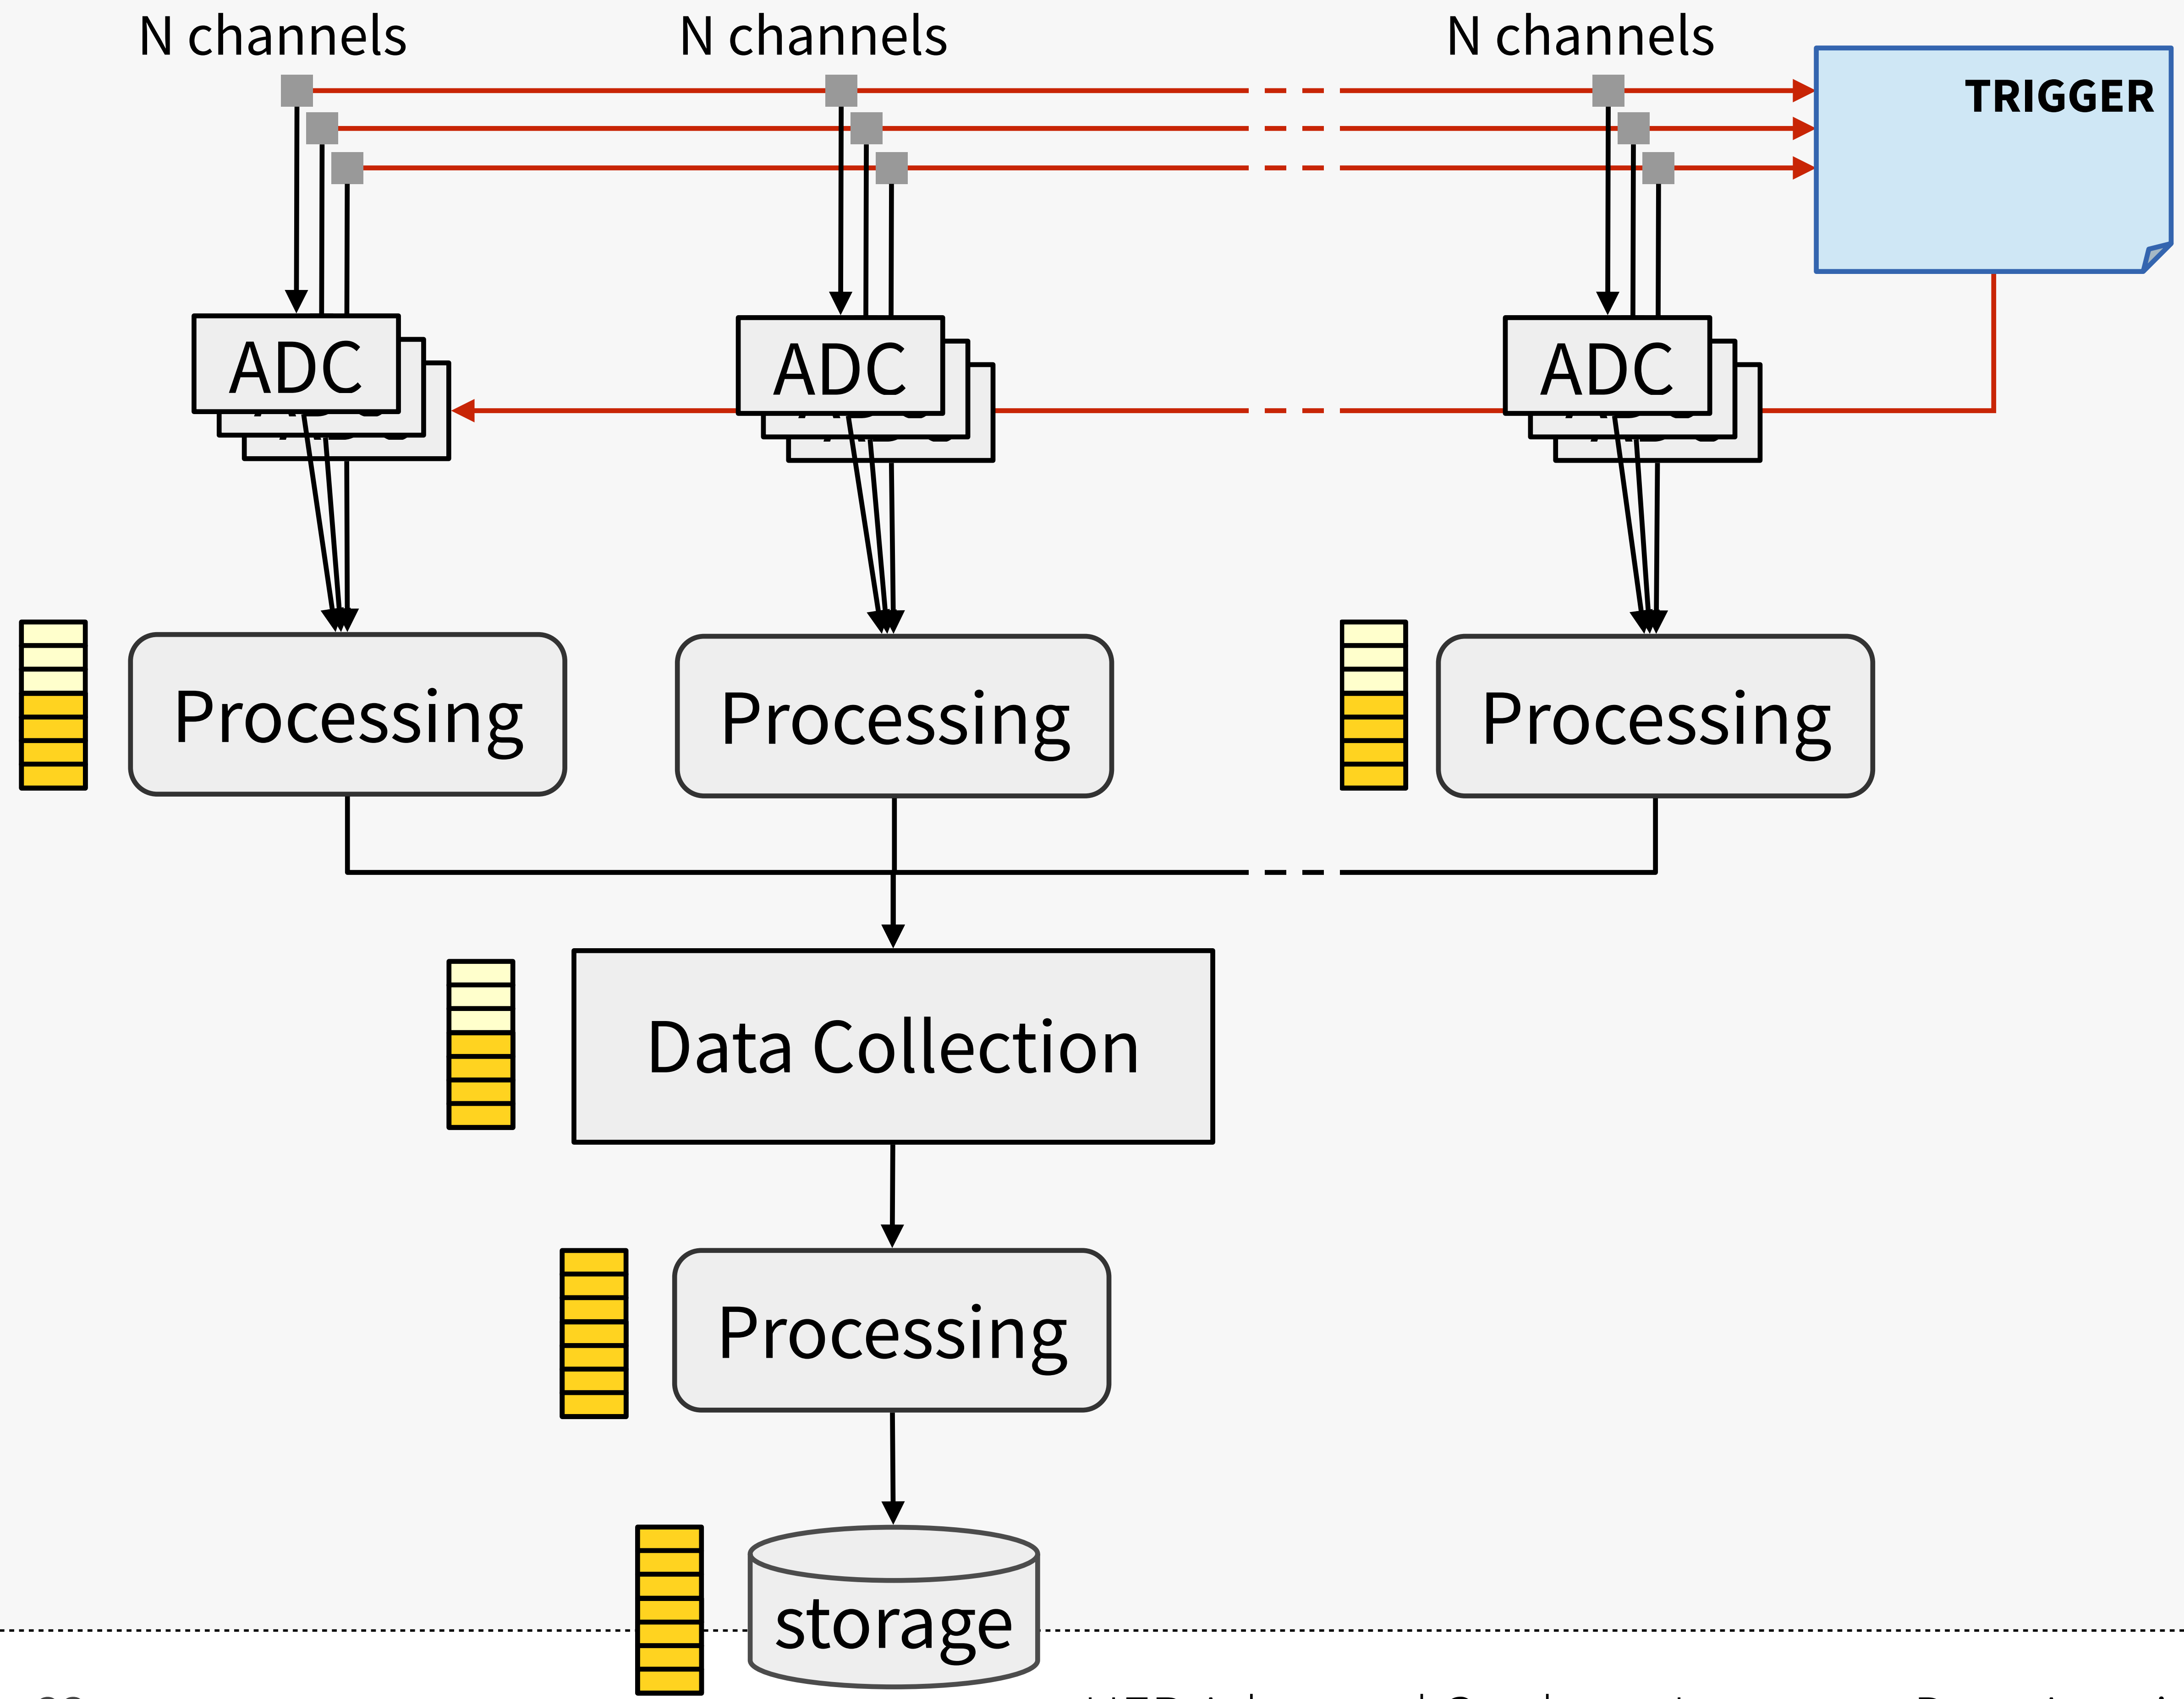
- the “pressure” is propagated upstream (**back-pressure**)



Backpressure

If a system/buffer gets saturated

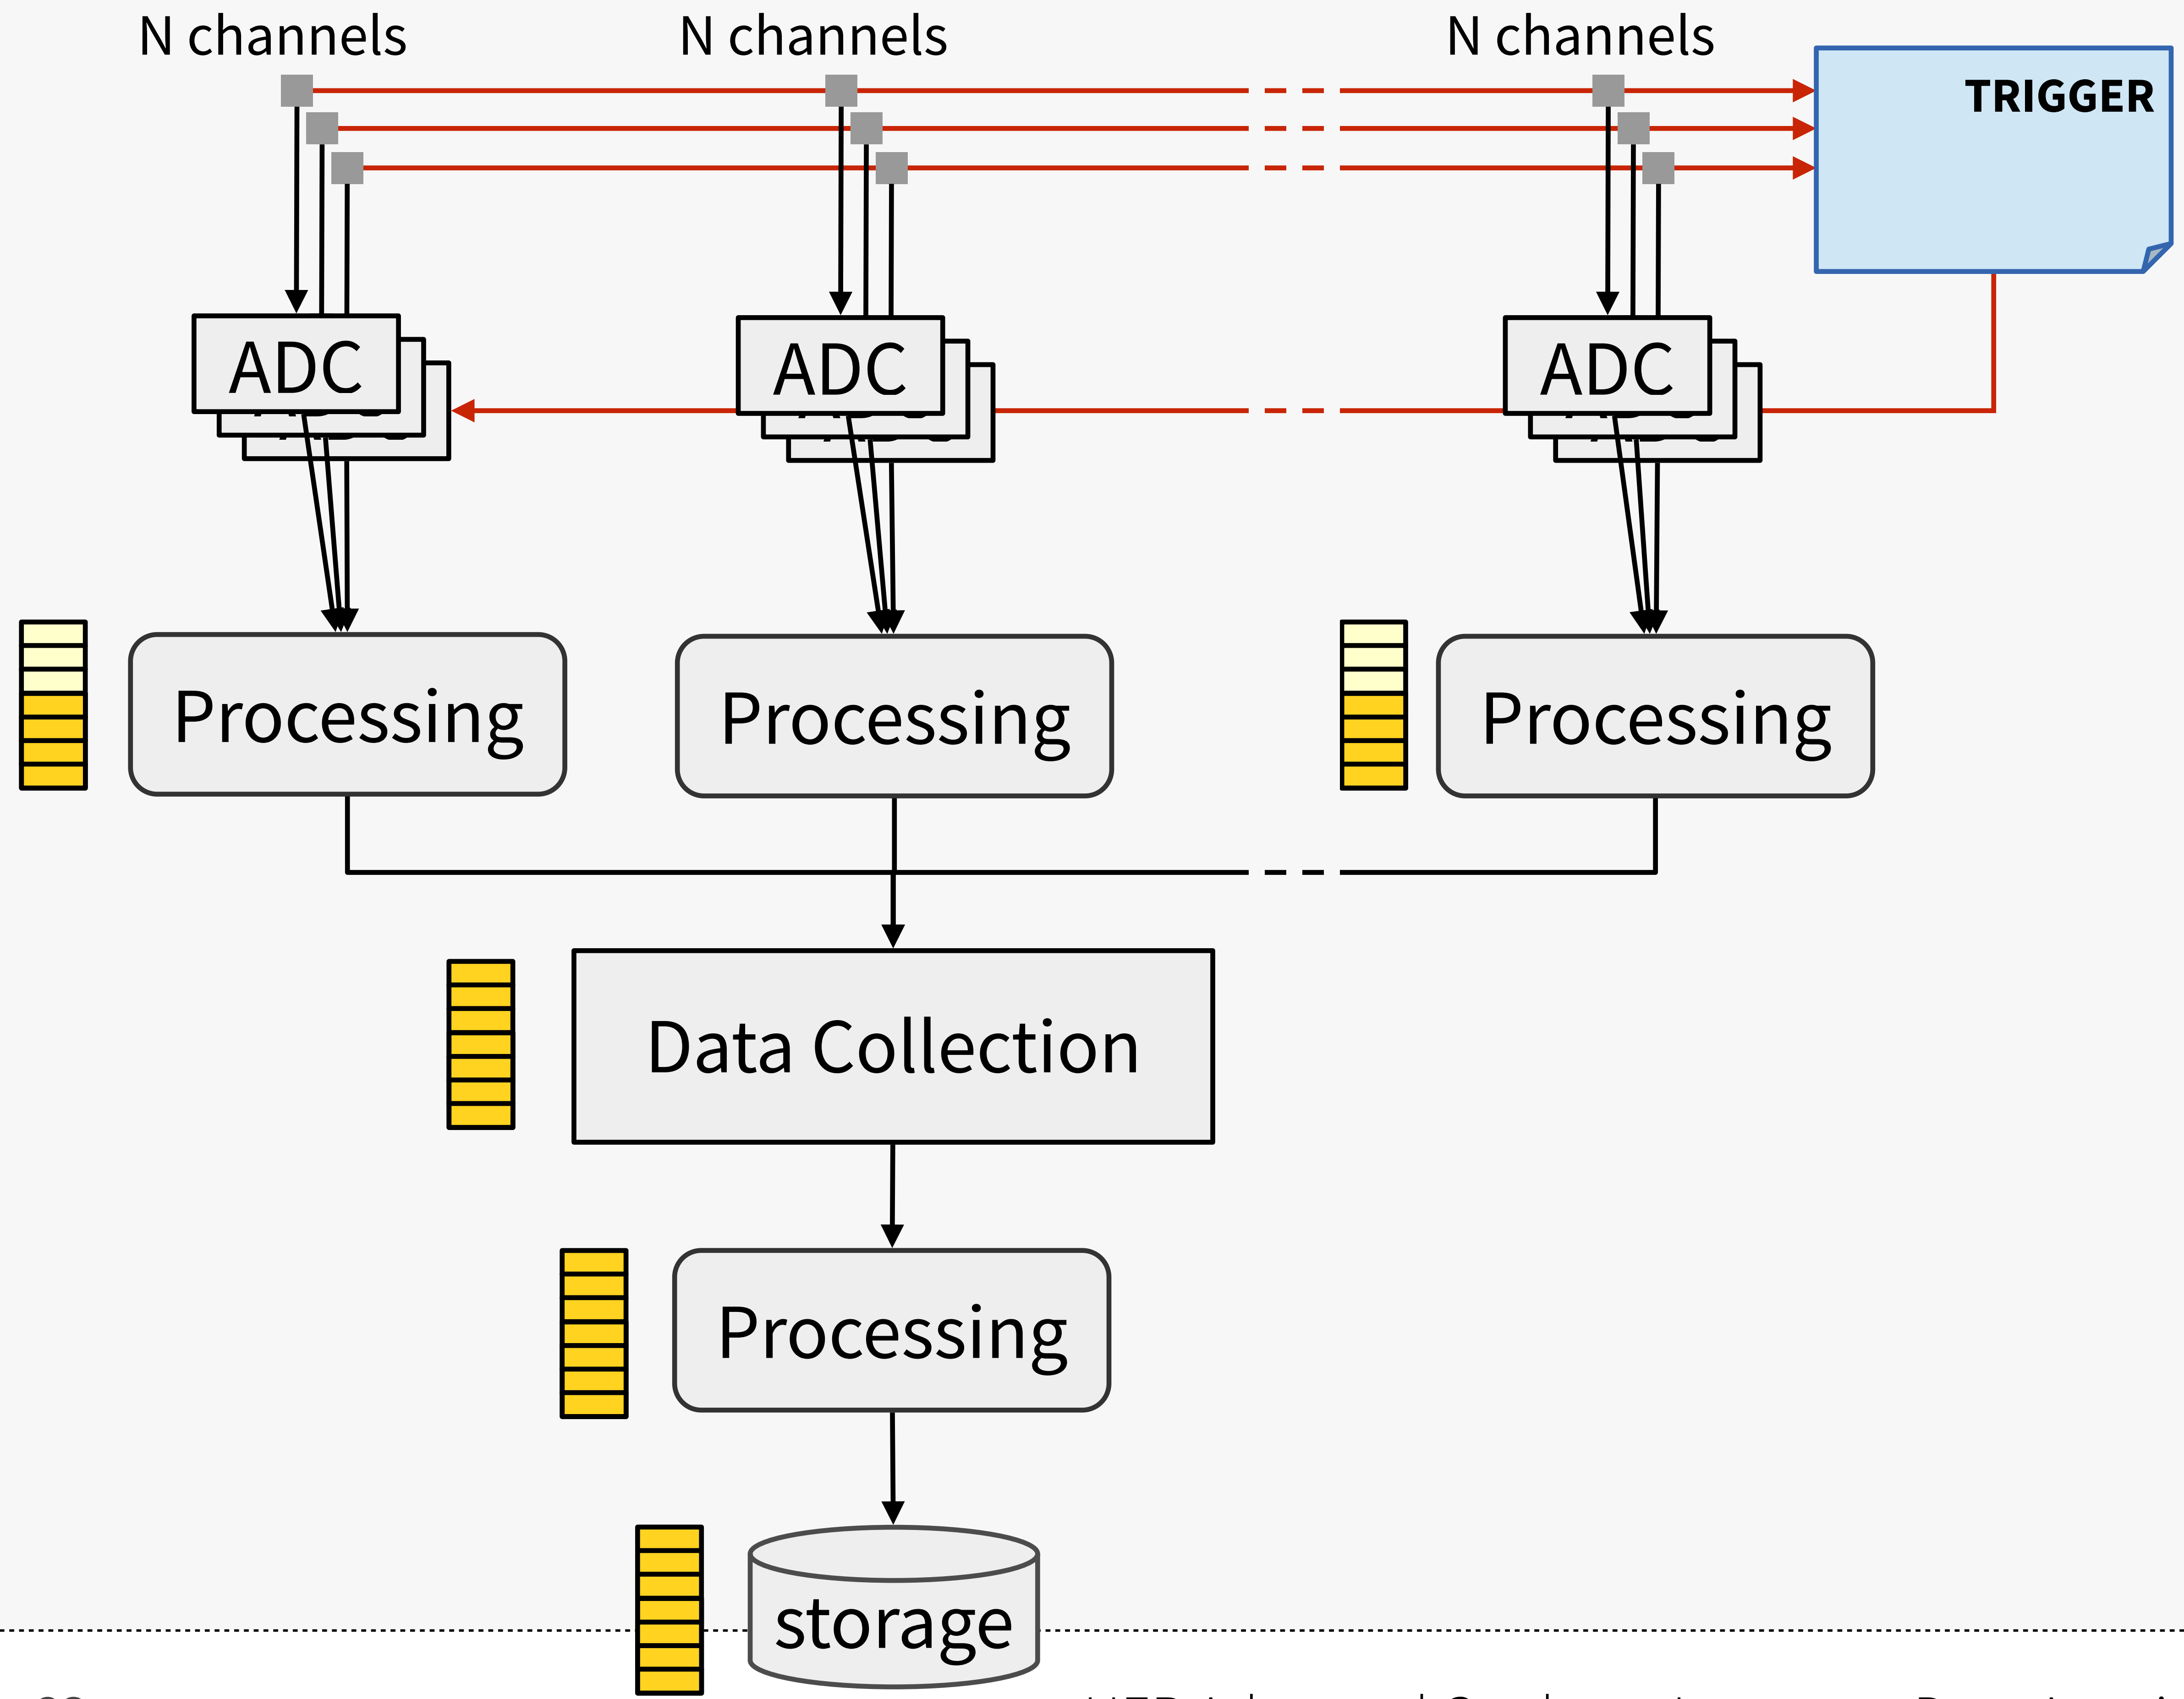
- the "pressure" is propagated upstream (**back-pressure**)



Backpressure

If a system/buffer gets saturated

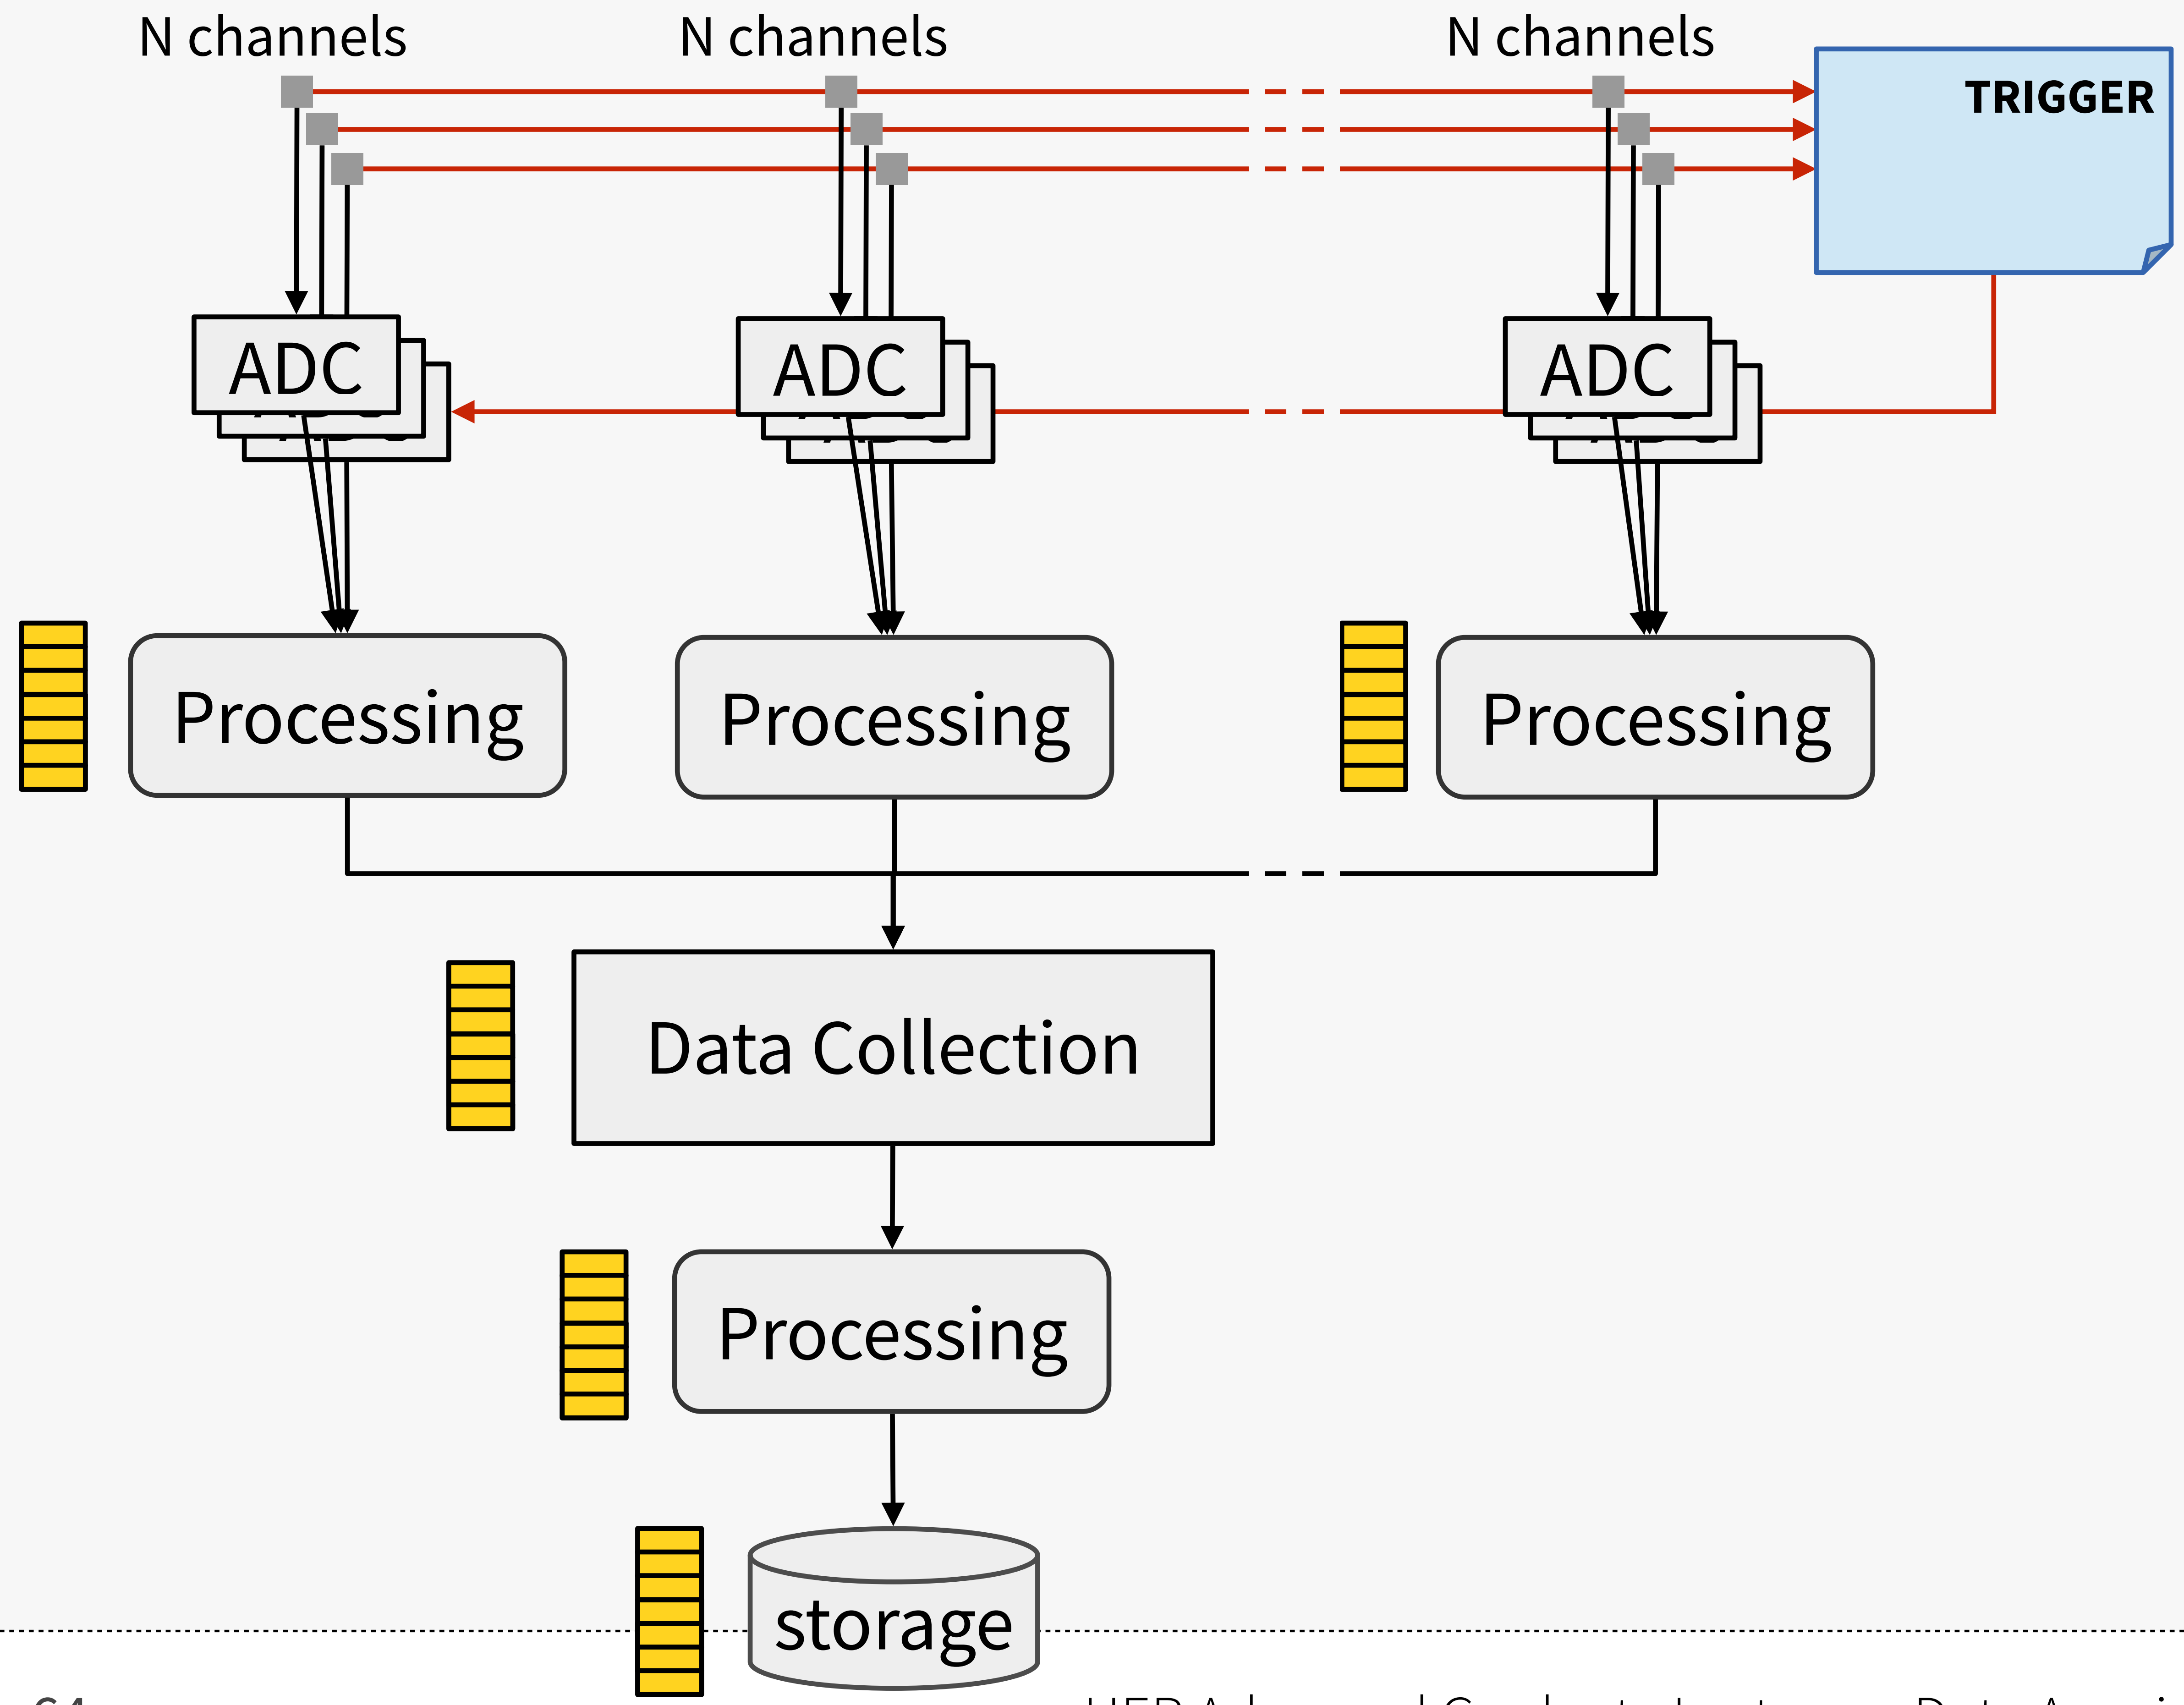
- the “pressure” is propagated upstream (**back-pressure**)



Backpressure

If a system/buffer gets saturated

- the "pressure" is propagated upstream (**back-pressure**)



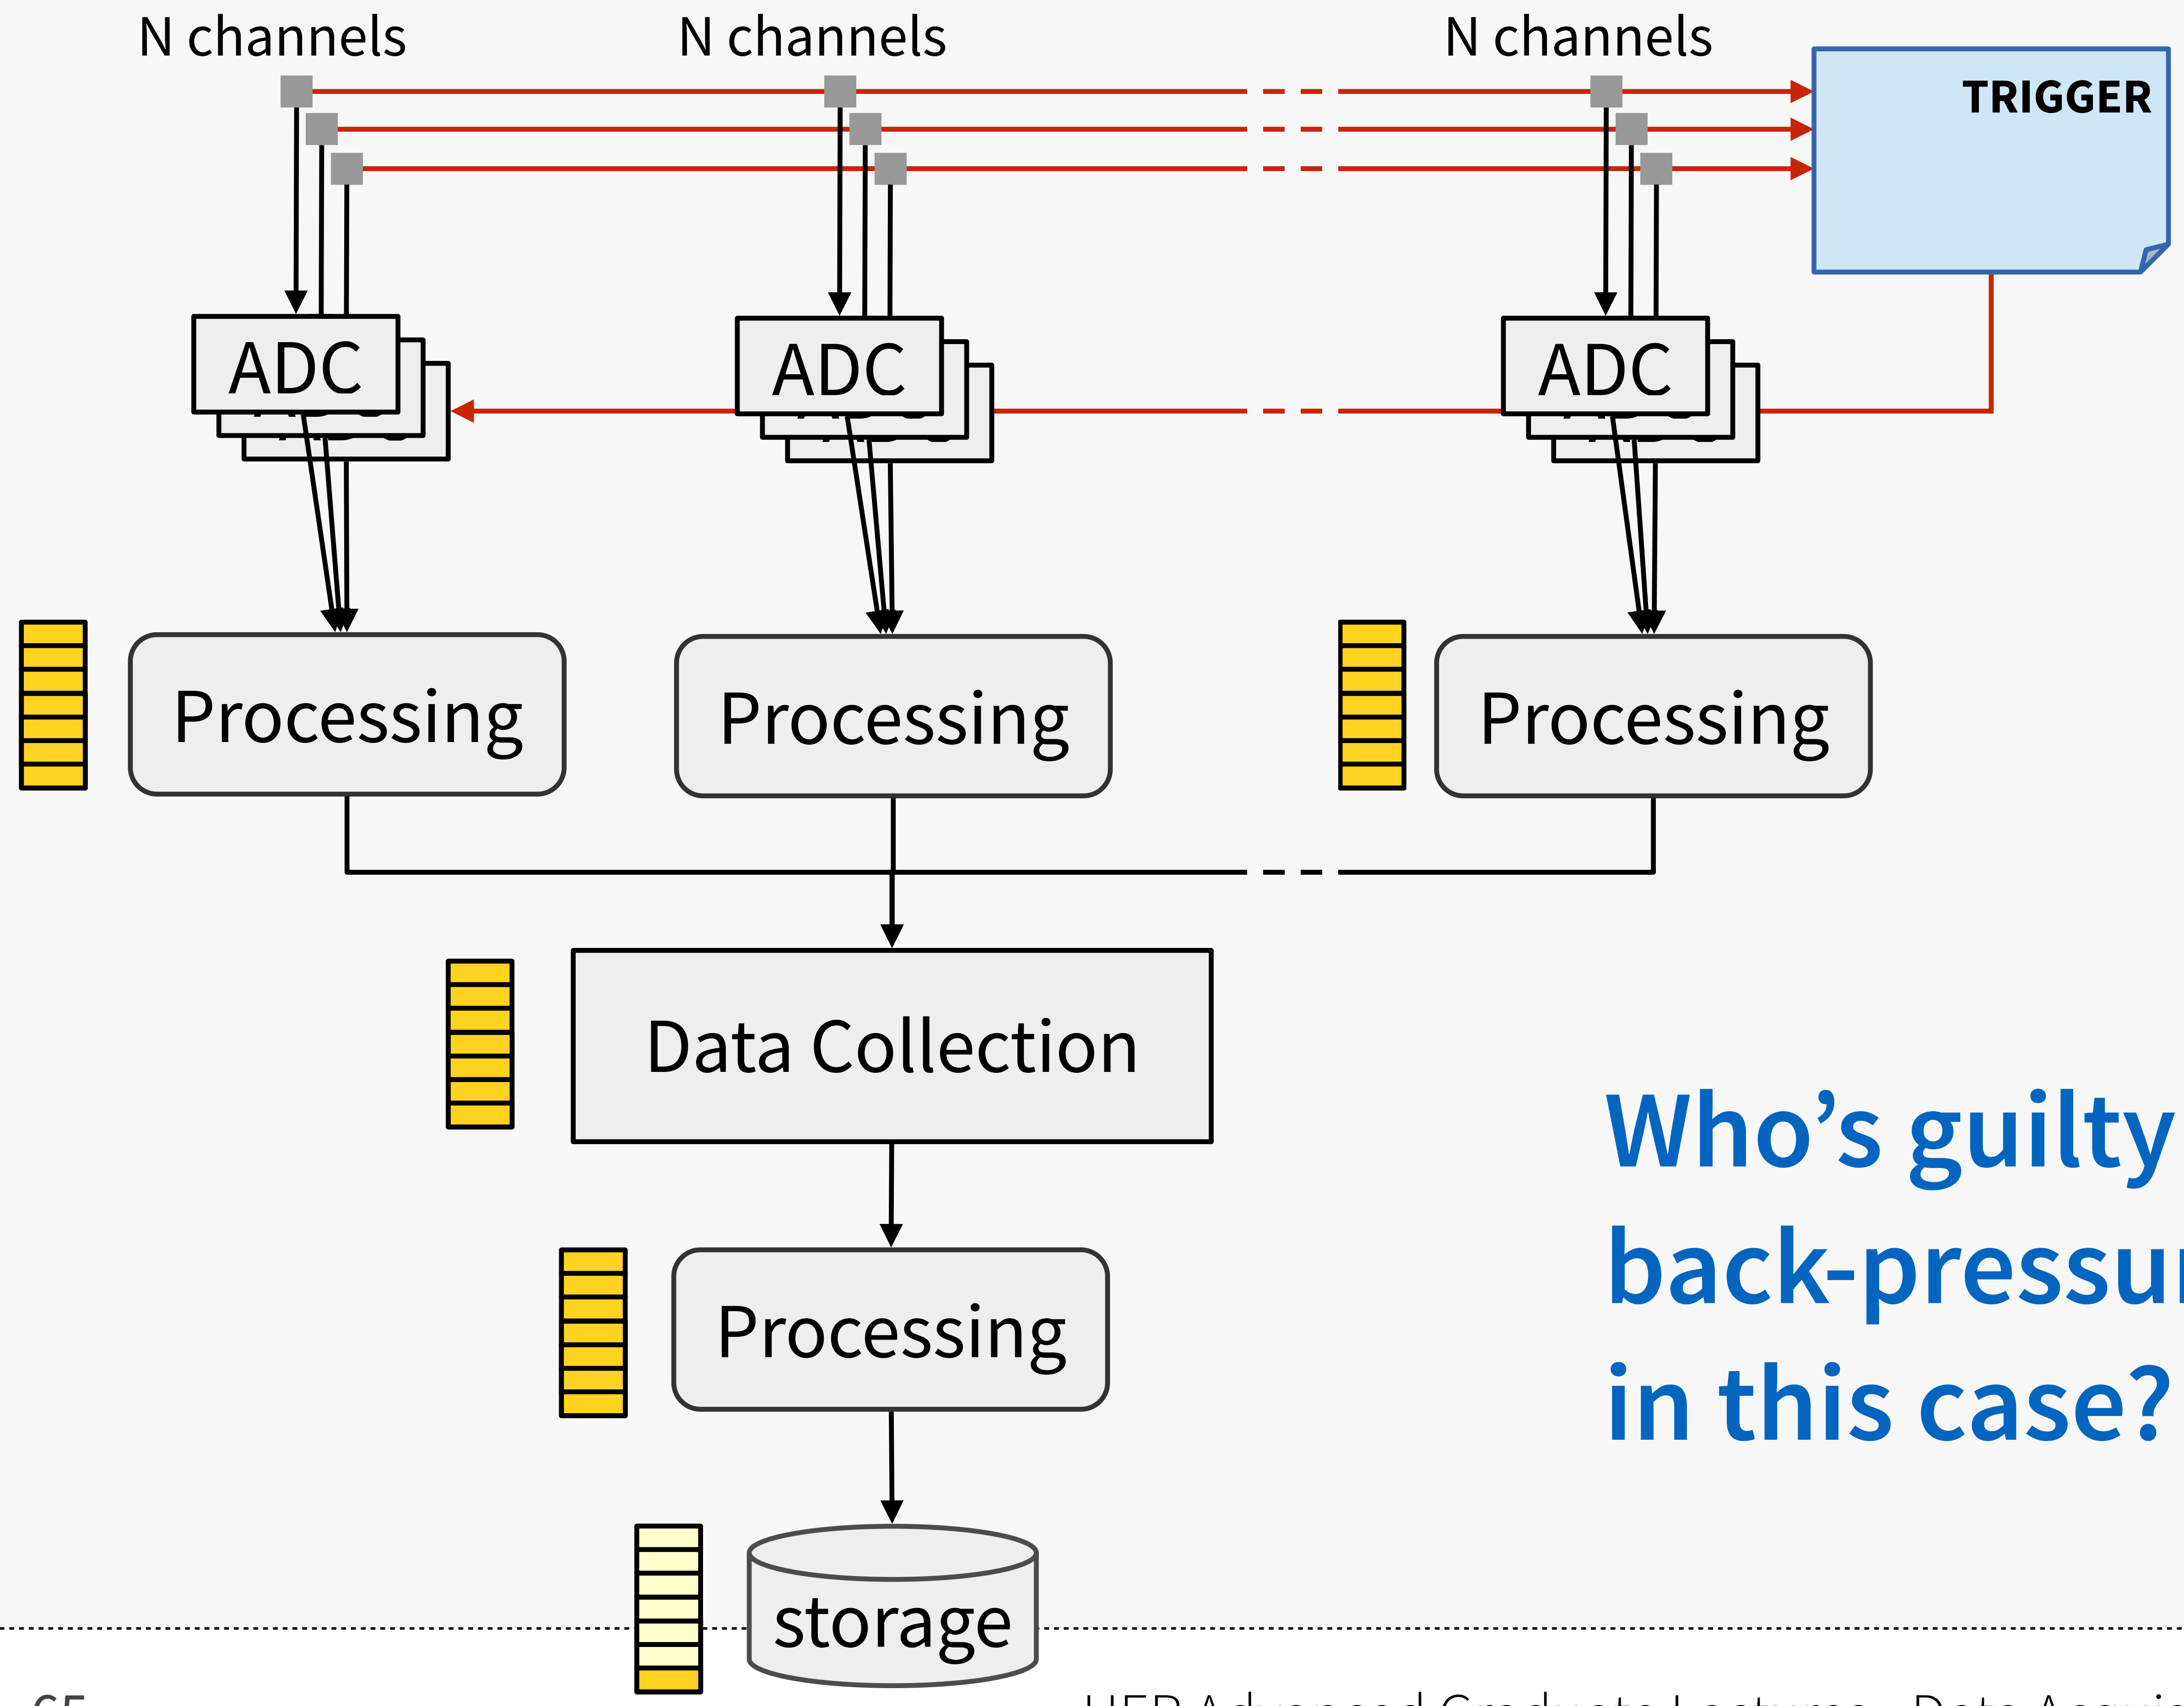
- Up to exert **busy** to the trigger system
- **Debugging**: where is the source of back-pressure?
  - follow the buffers occupancy via the monitoring system

Science and Technology Facilities Council

Backpressure

If a system/buffer gets saturated

- the "pressure" is propagated upstream (**back-pressure**)

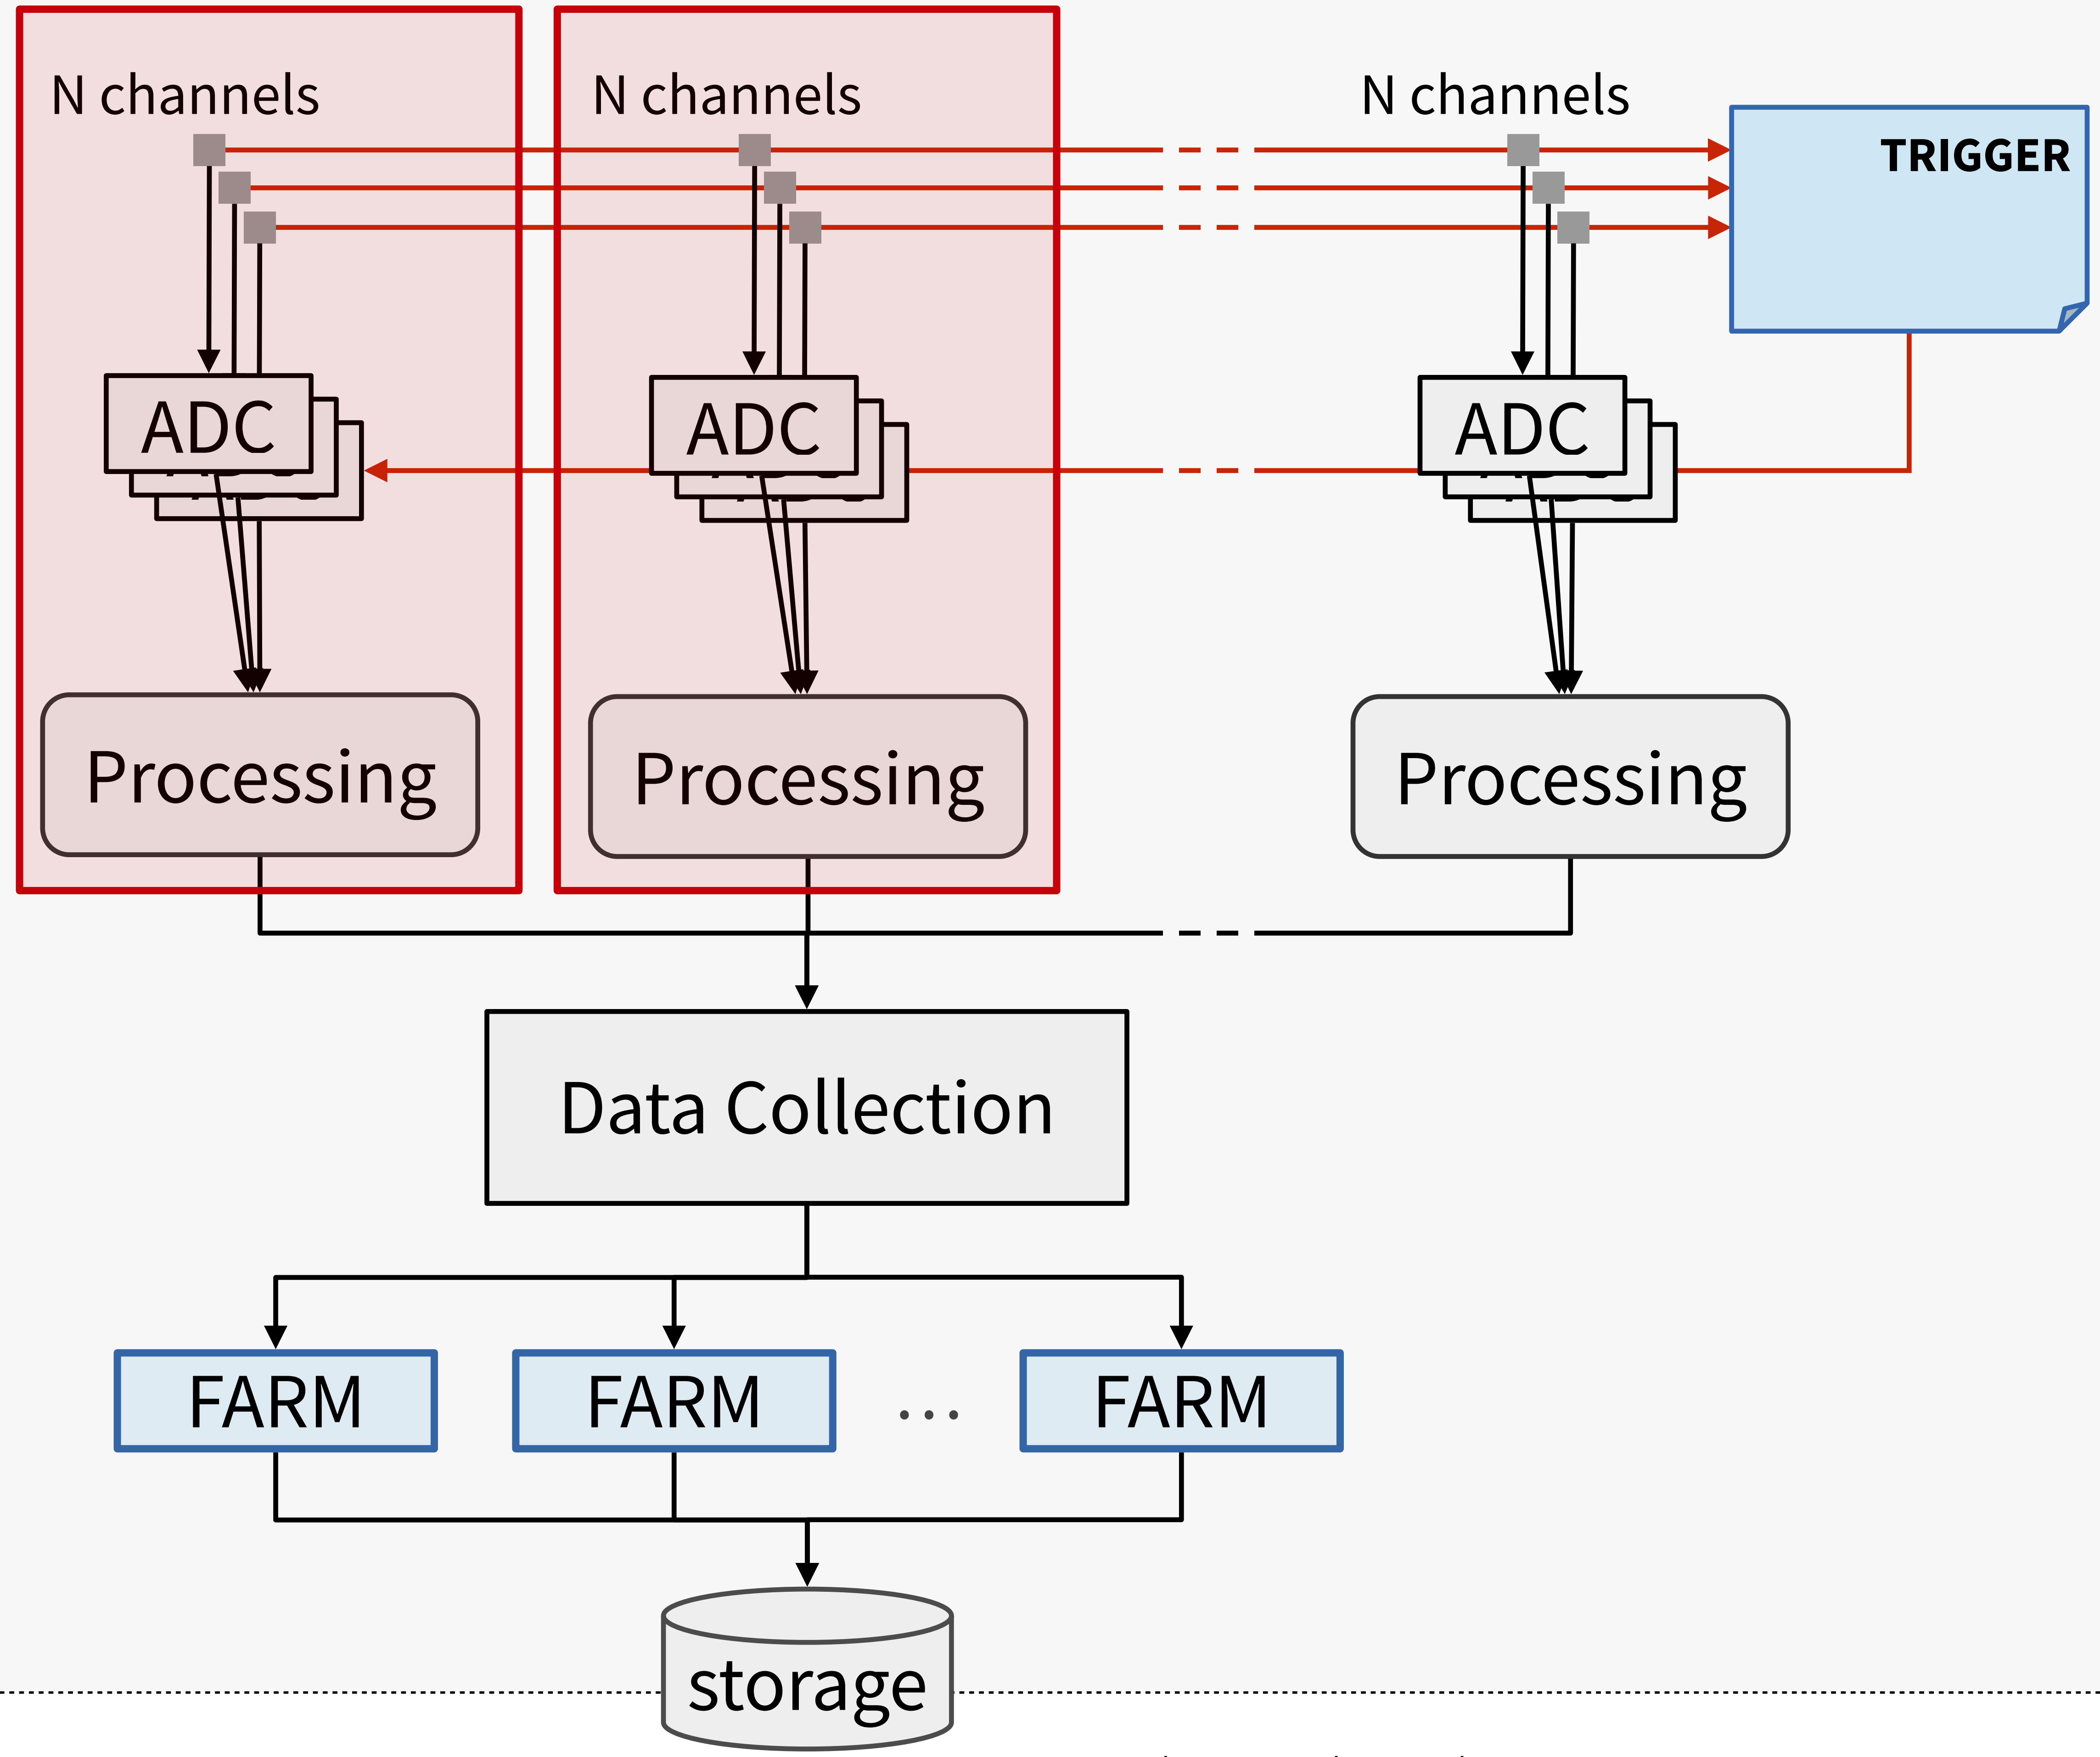


- Up to exert **busy** to the trigger system
- **Debugging**: where is the source of back-pressure?
  - follow the buffers occupancy via the monitoring system

Who's guilty of back-pressure in this case?

Building blocks

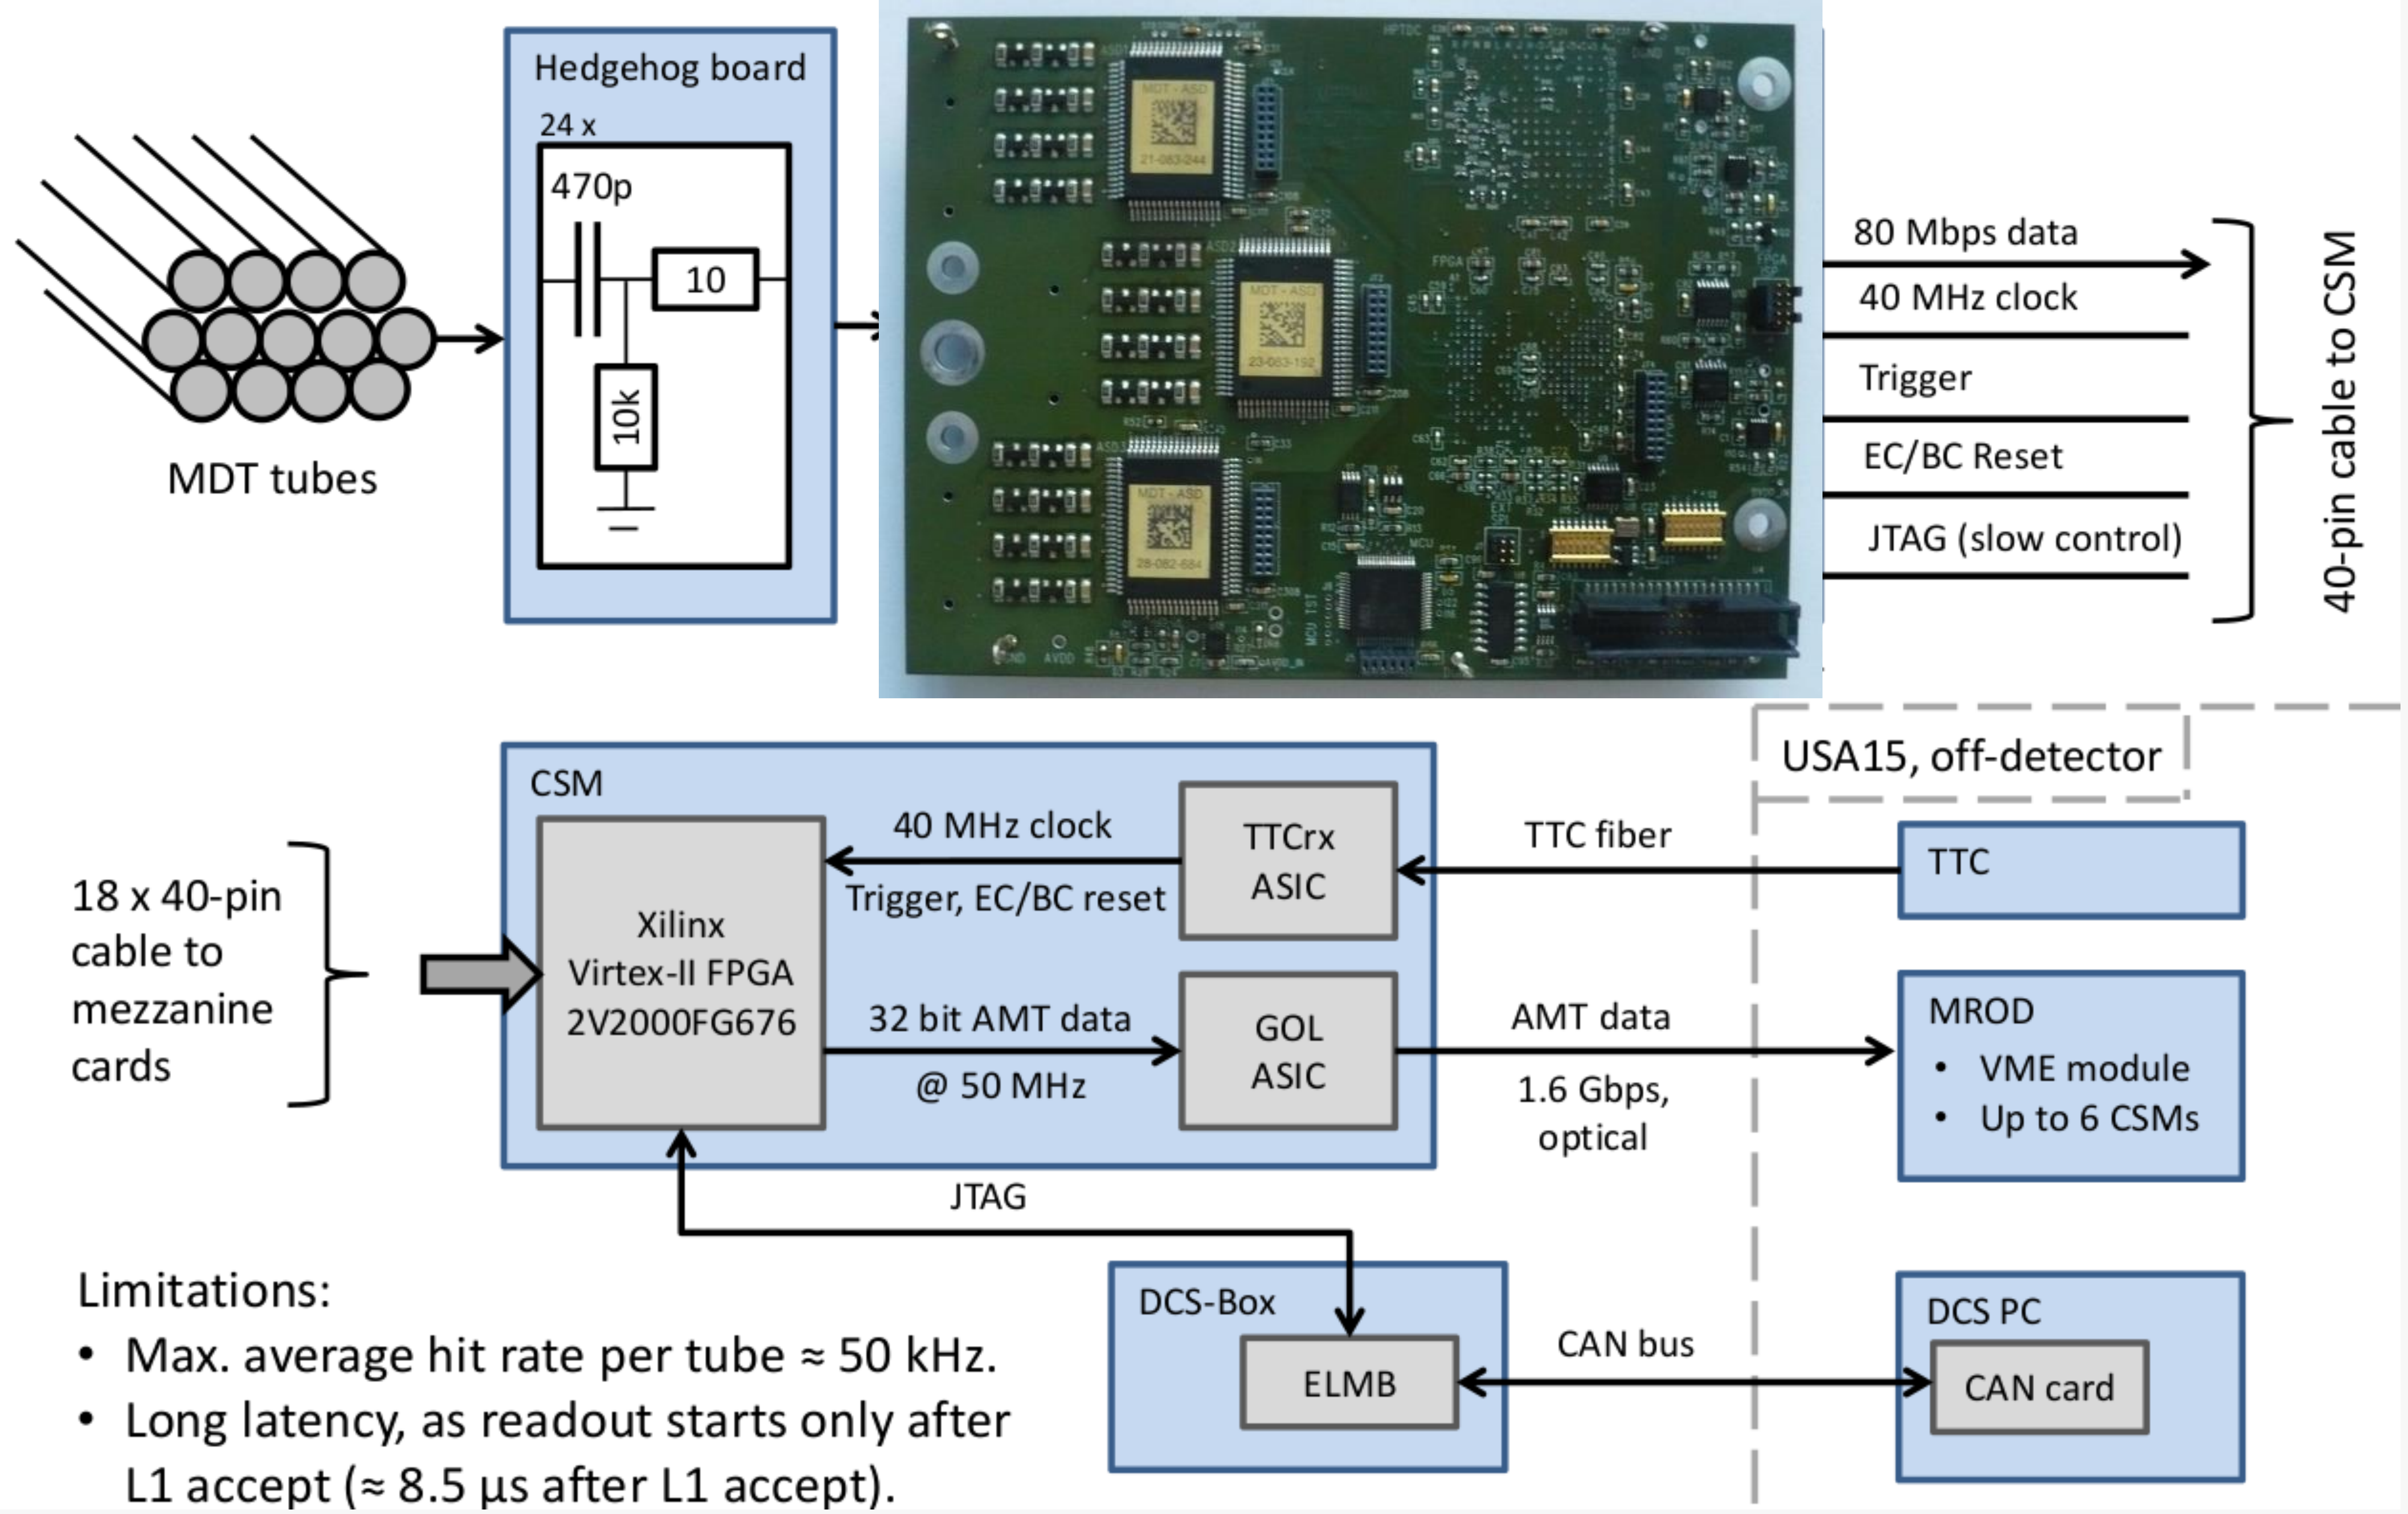
Reading out data or building events out of many channels requires many components



In the design of our hierarchical data-collection system, it's convenient to define "**building blocks**"

- **Readout crates**
- **HLT racks**
- **event building groups**
- **daq slices**

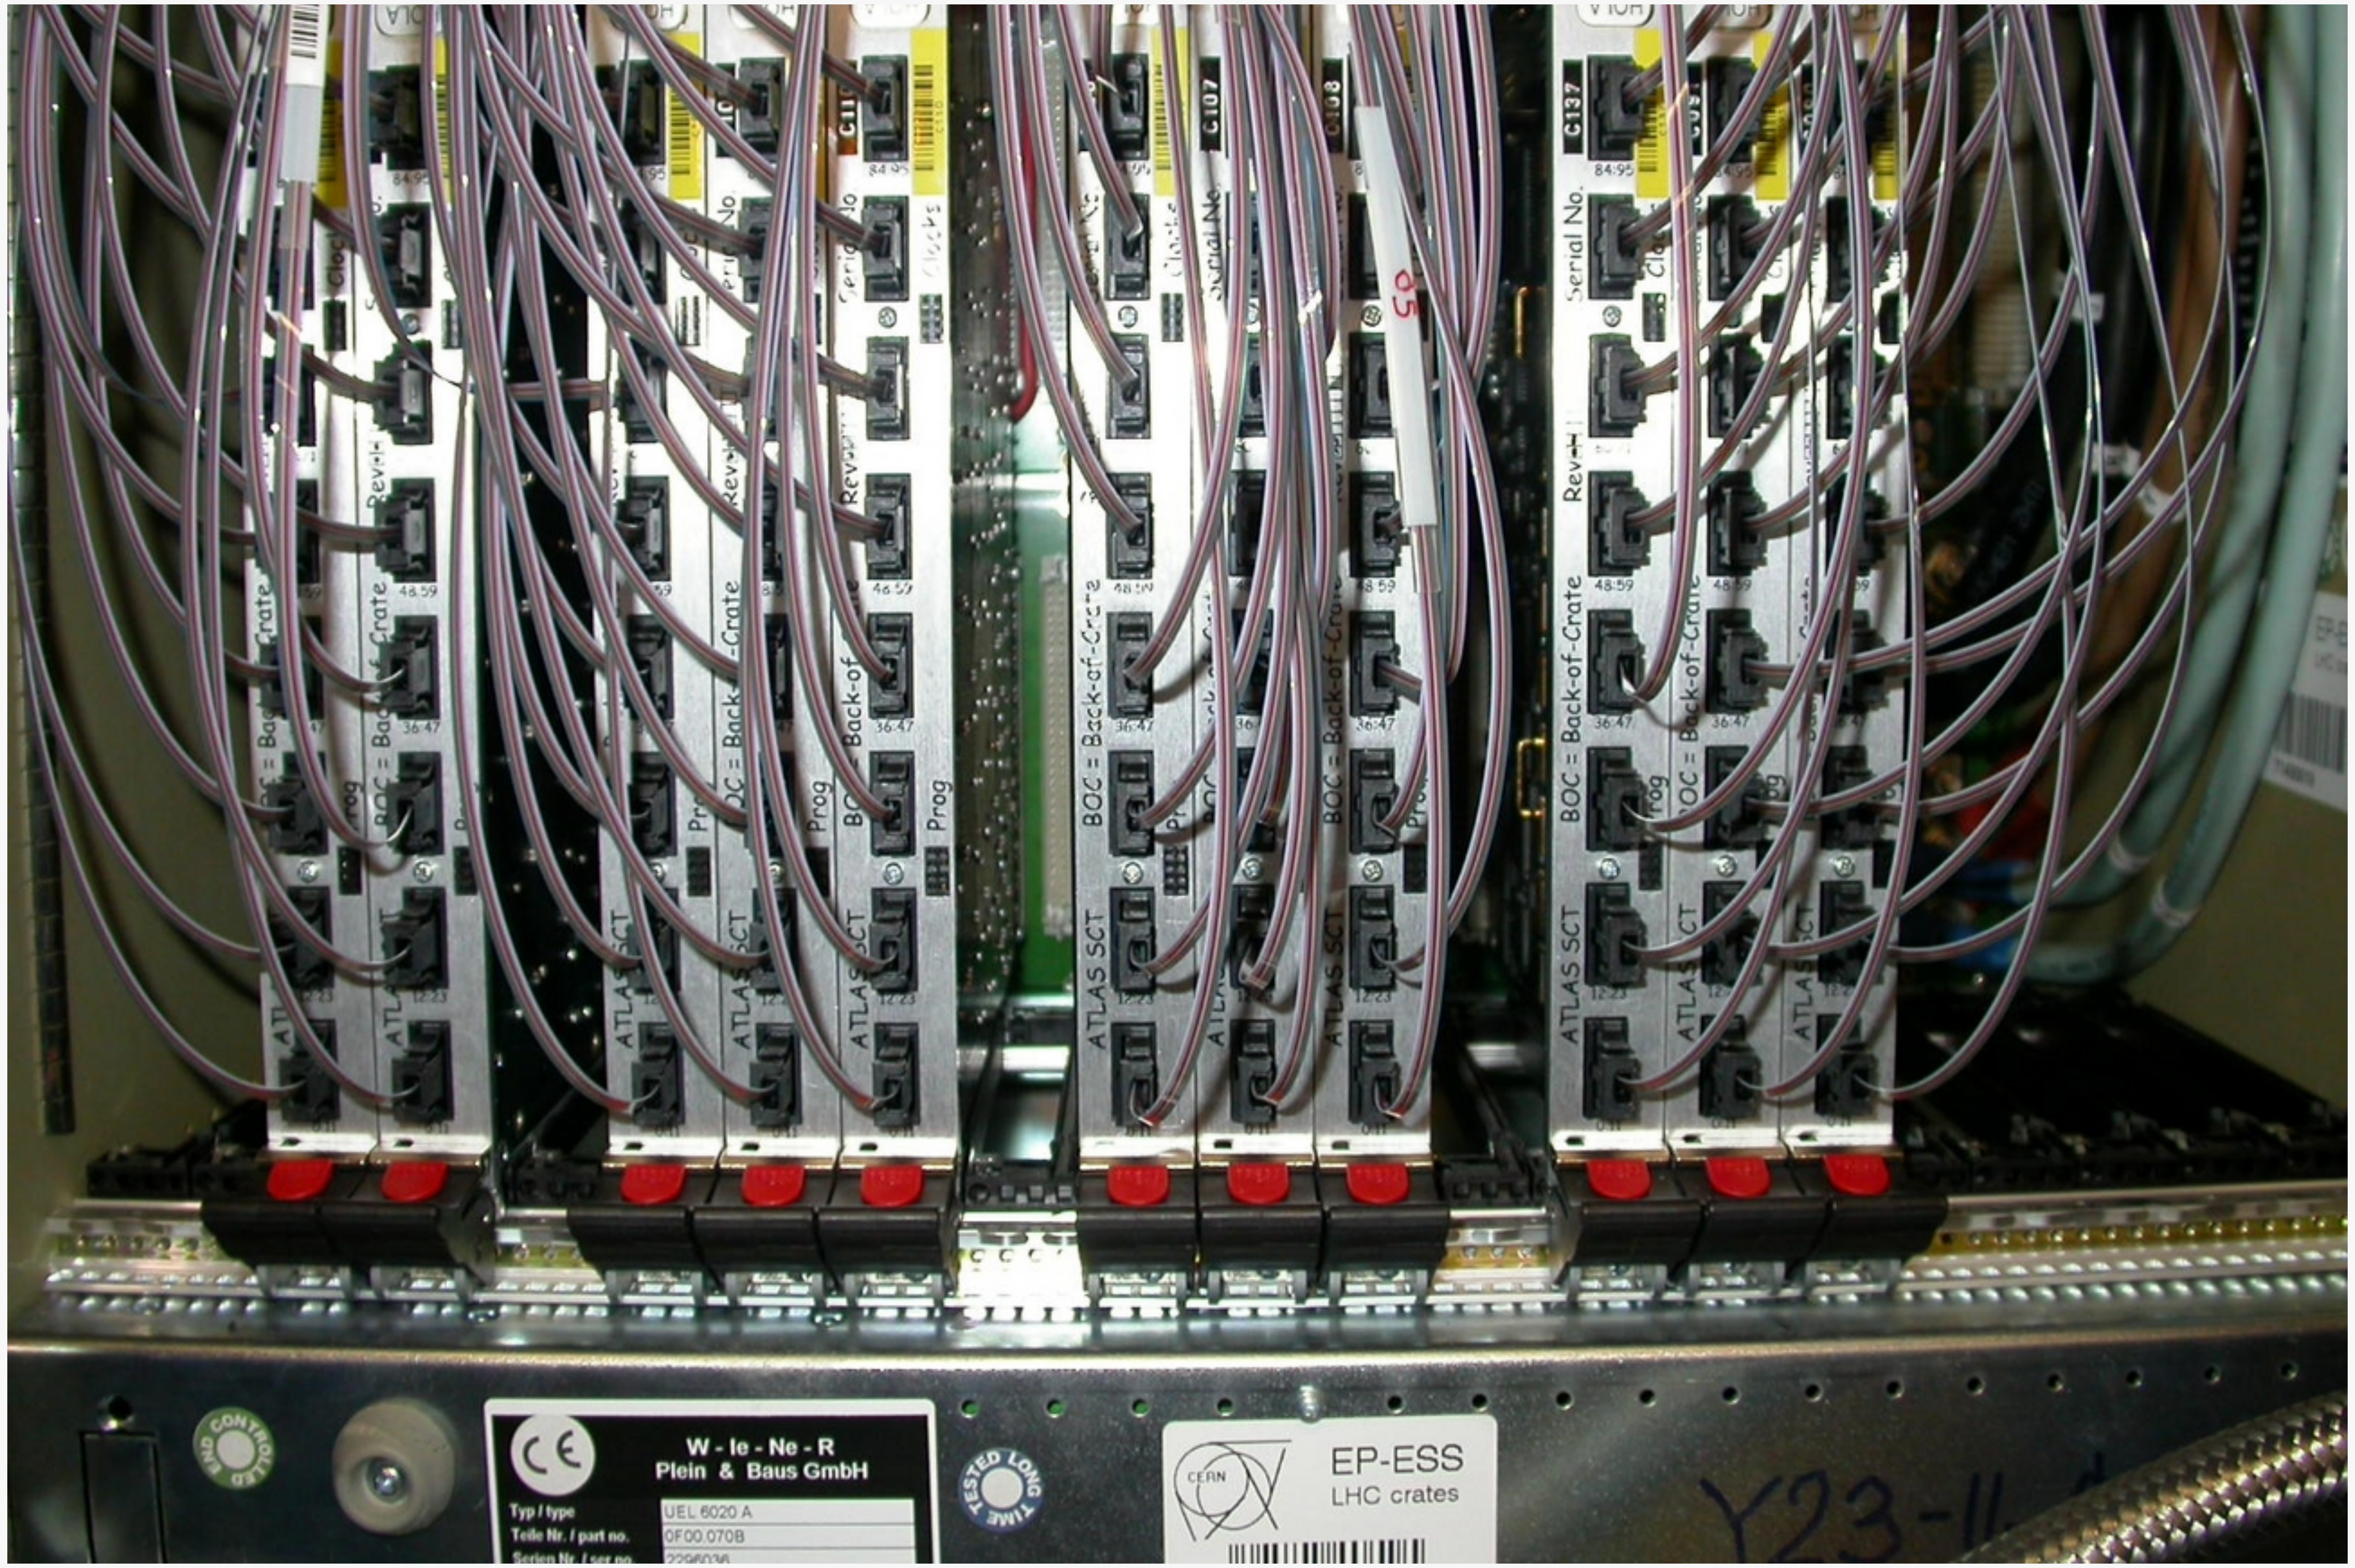
Front End electronics



Limitations:

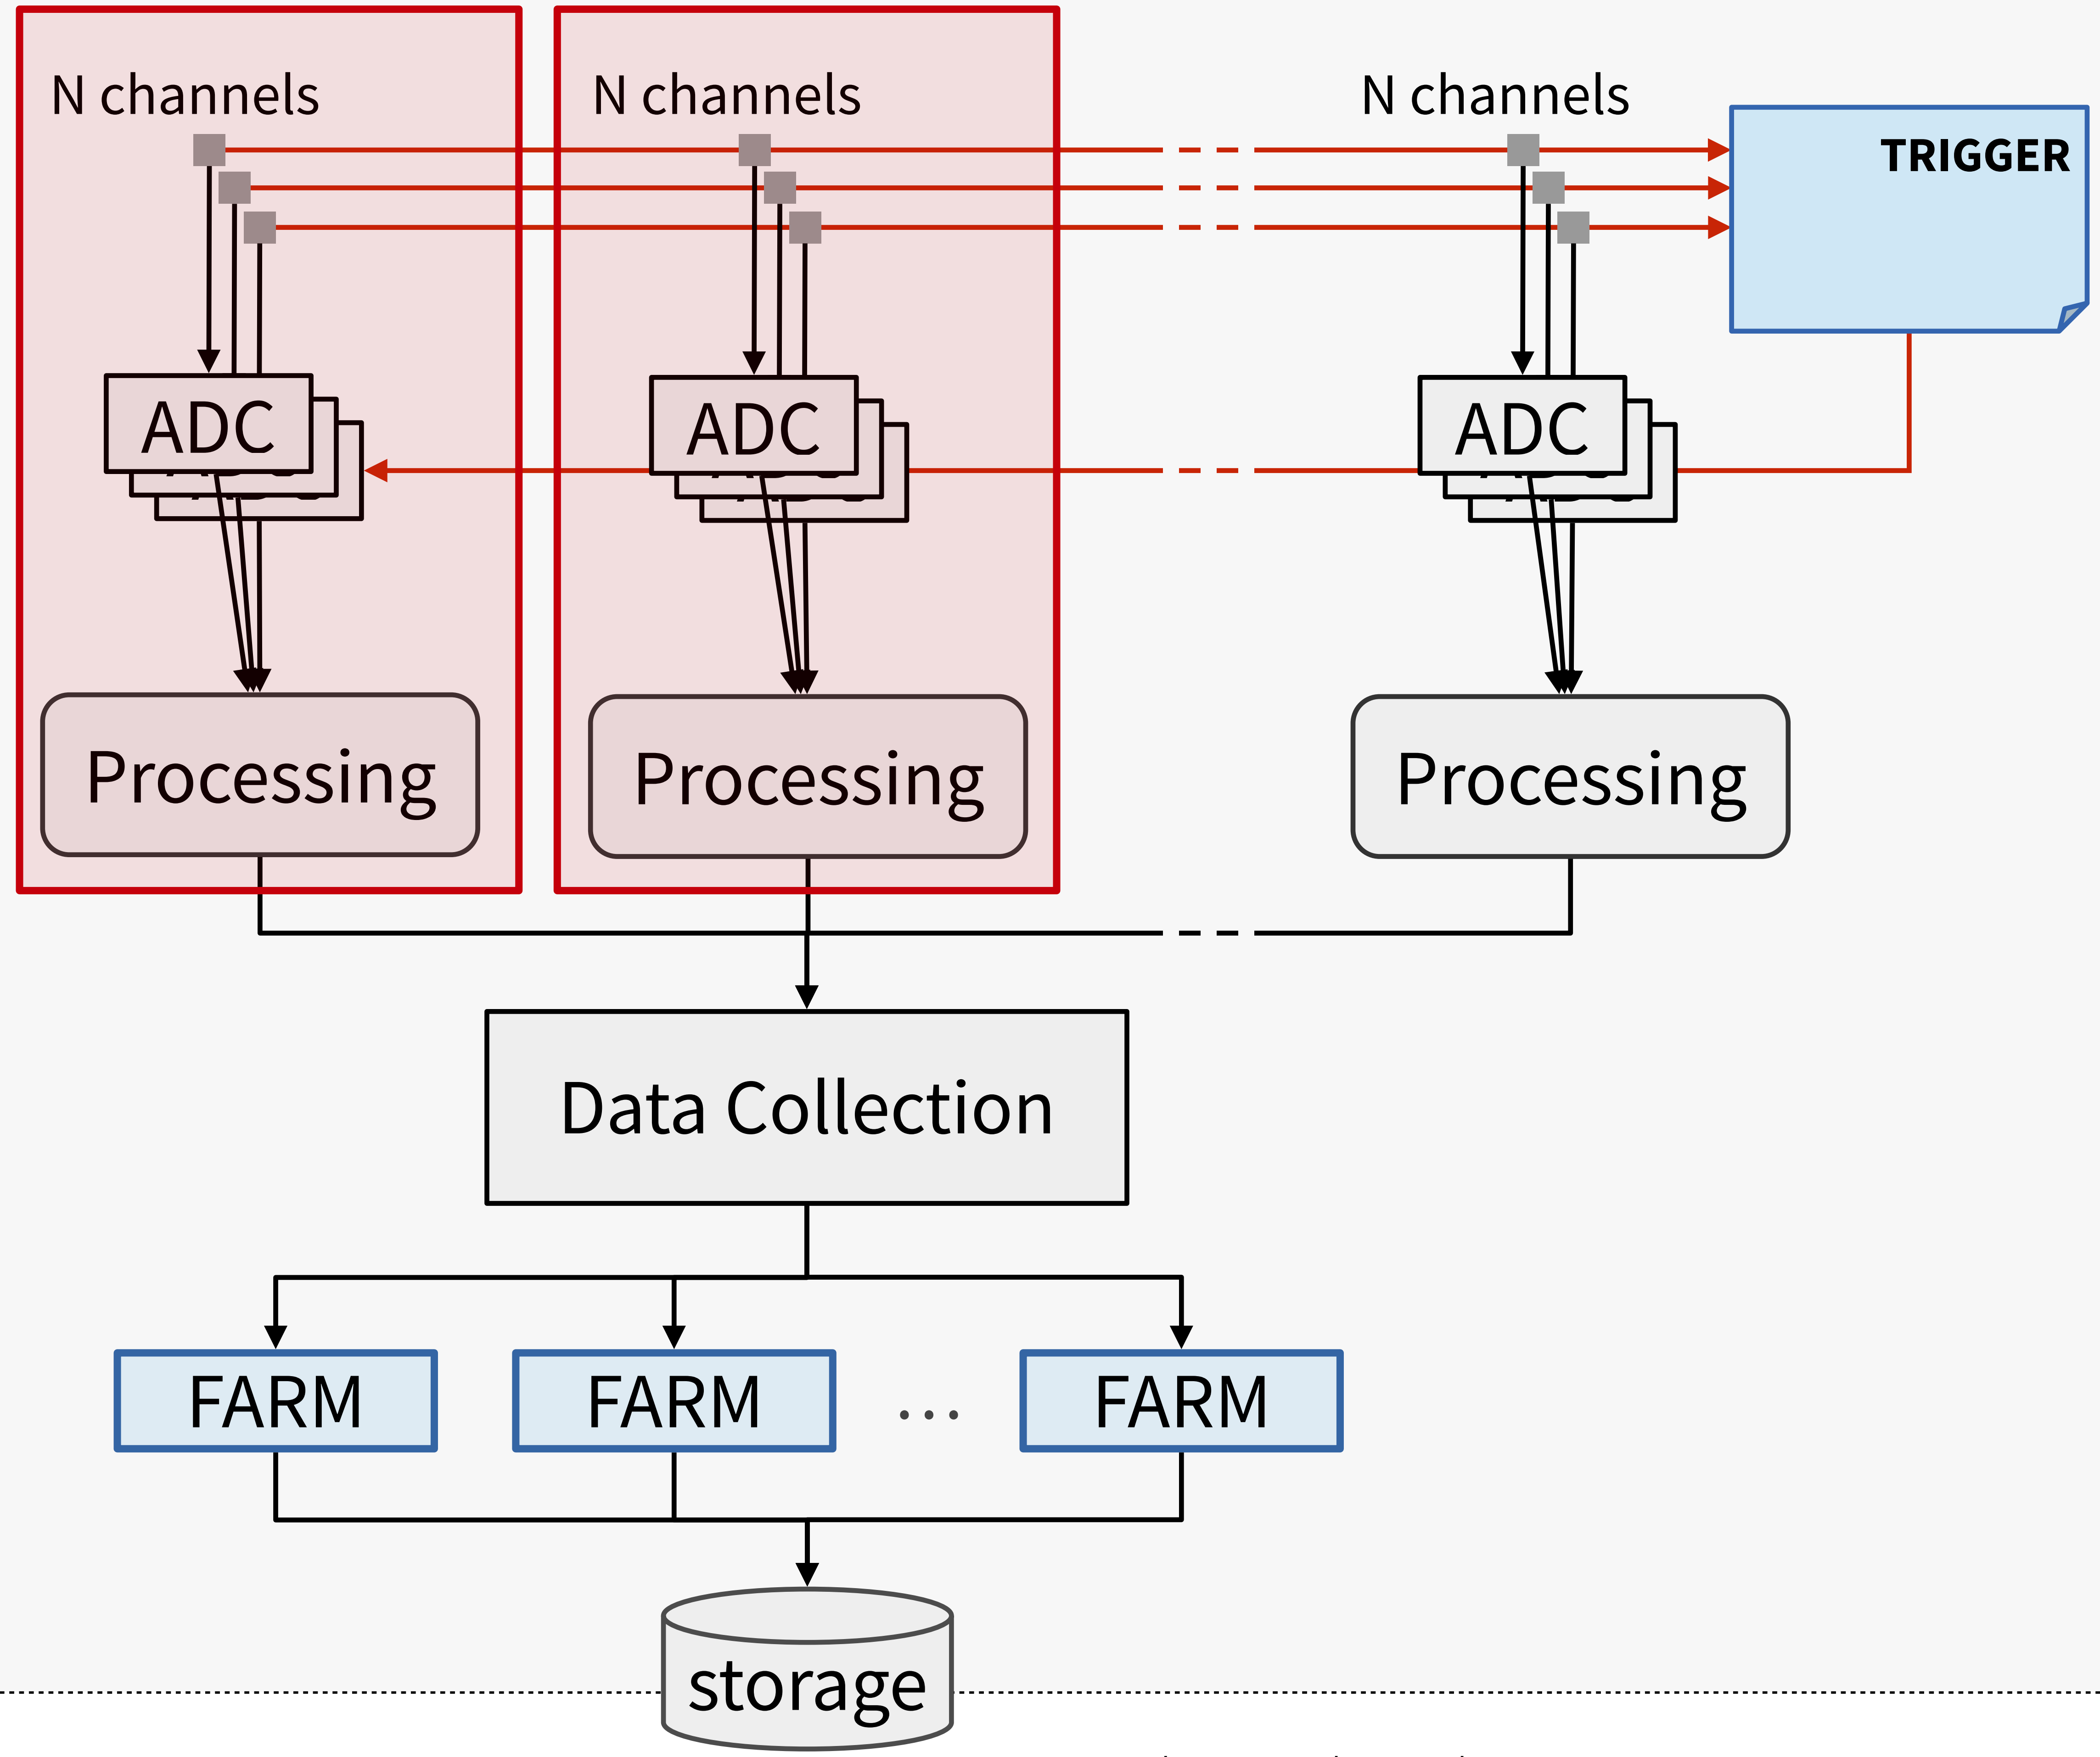
- Max. average hit rate per tube ≈ 50 kHz.
- Long latency, as readout starts only after L1 accept (≈ 8.5 μs after L1 accept).

Readout Boards (Counting Room)



Building blocks

Reading out data or building events out of many channels requires many components



In the design of our hierarchical data-collection system, it's convenient to define "**building blocks**"

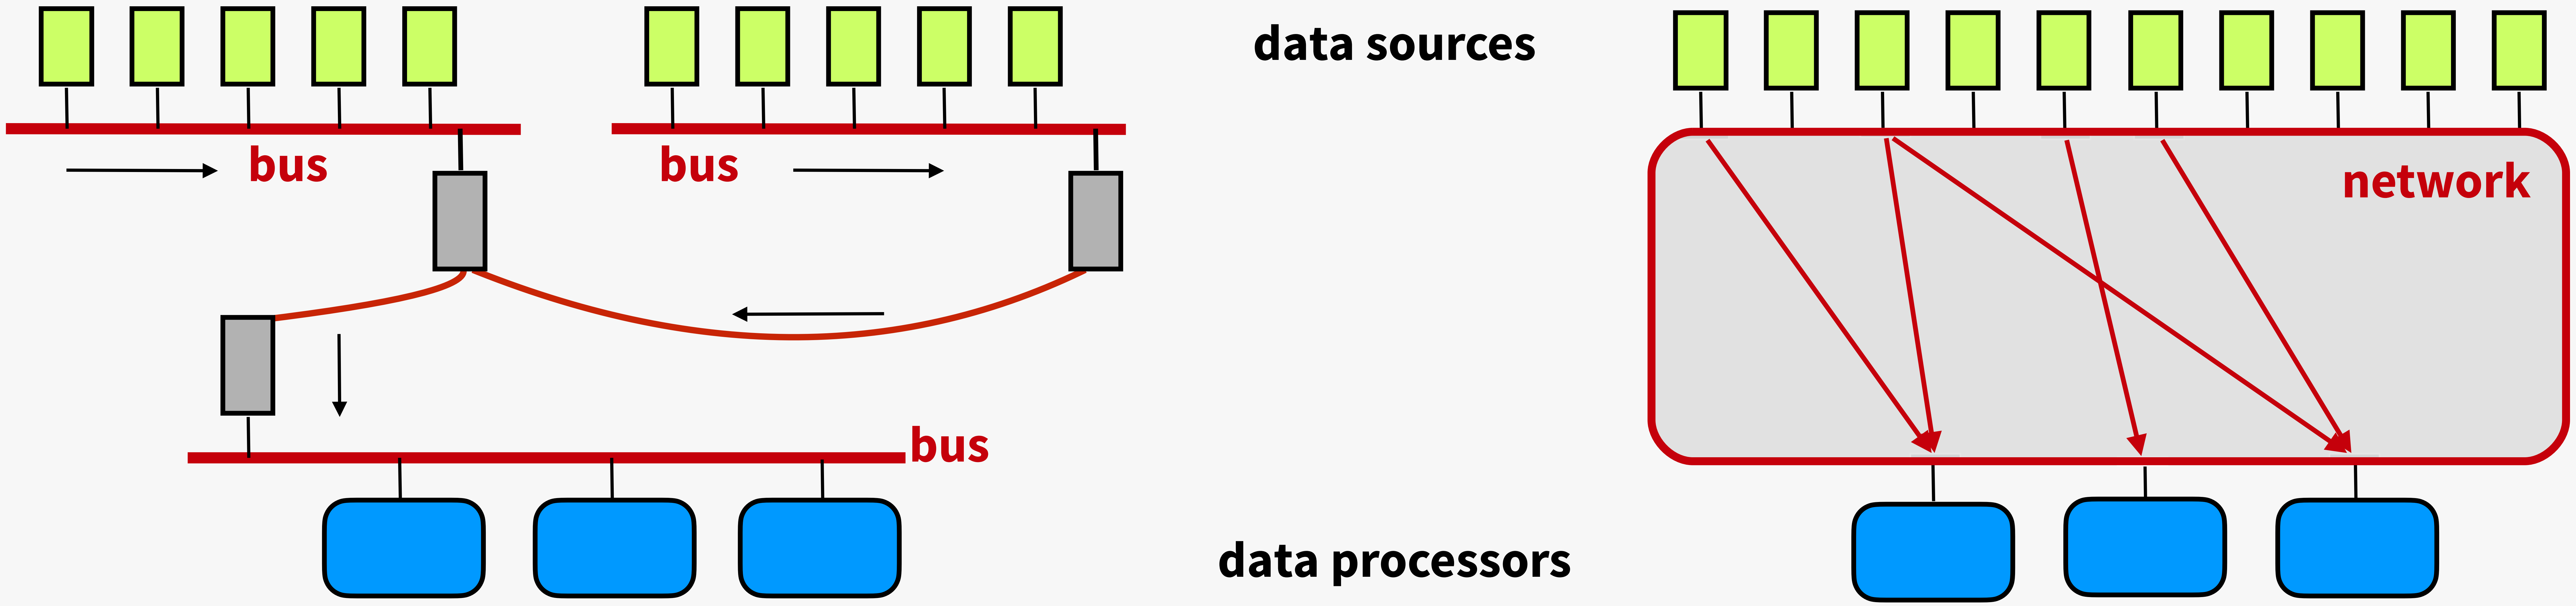
- **Readout crates**
- **HLT racks**
- **event building groups**
- **daq slices**

Farm (@surface)

Readout Topology

How to organize interconnections inside the building blocks and between building blocks?

- How to connect data sources and data destinations?
- Two main classes: **bus** or **network**



Buses

Devices connected via a **shared bus**

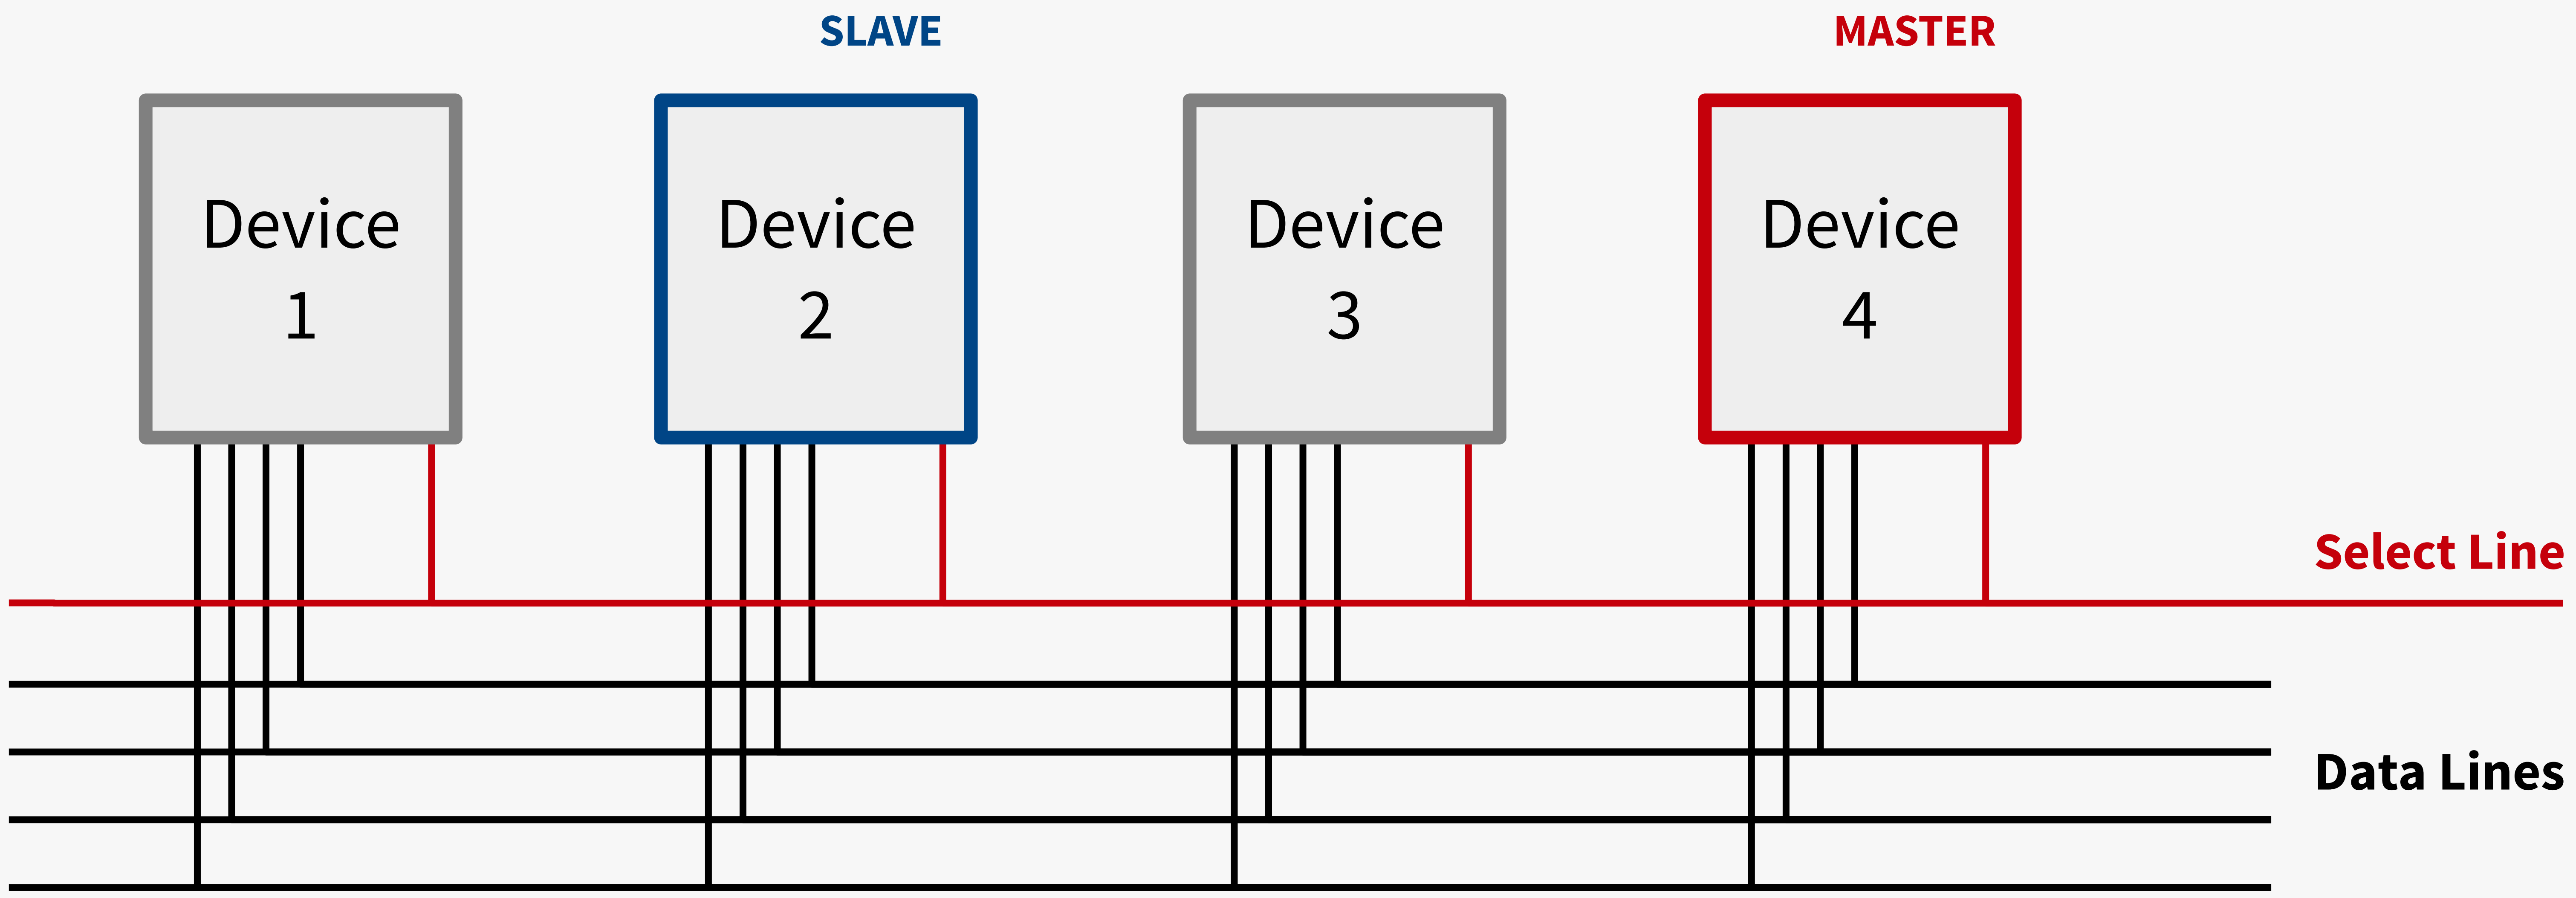
- Bus → group of electrical lines

Sharing implies **arbitration**

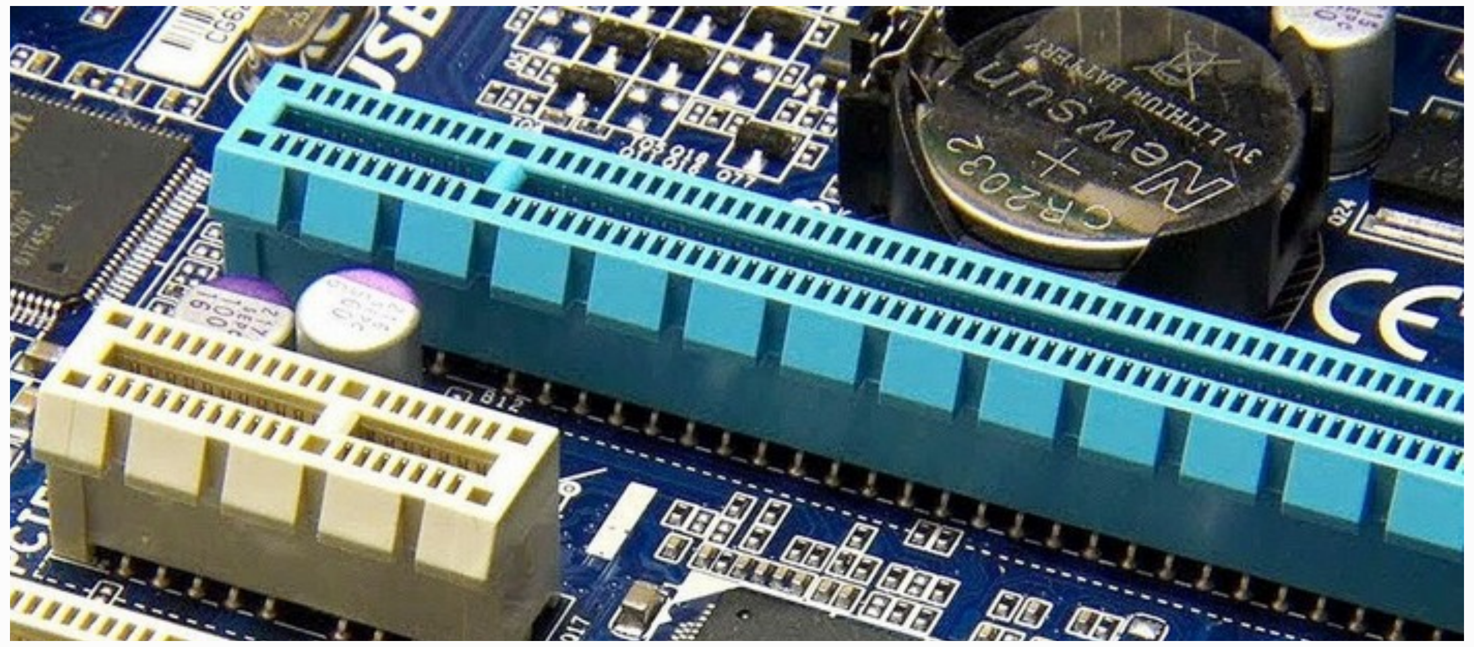
- Devices can be **master** or **slave**
- Devices can be addresses (uniquely identified) on the bus

E.g.: SCSI, Parallel ATA, VME, PCI …

- local, external, crate, long distance, …

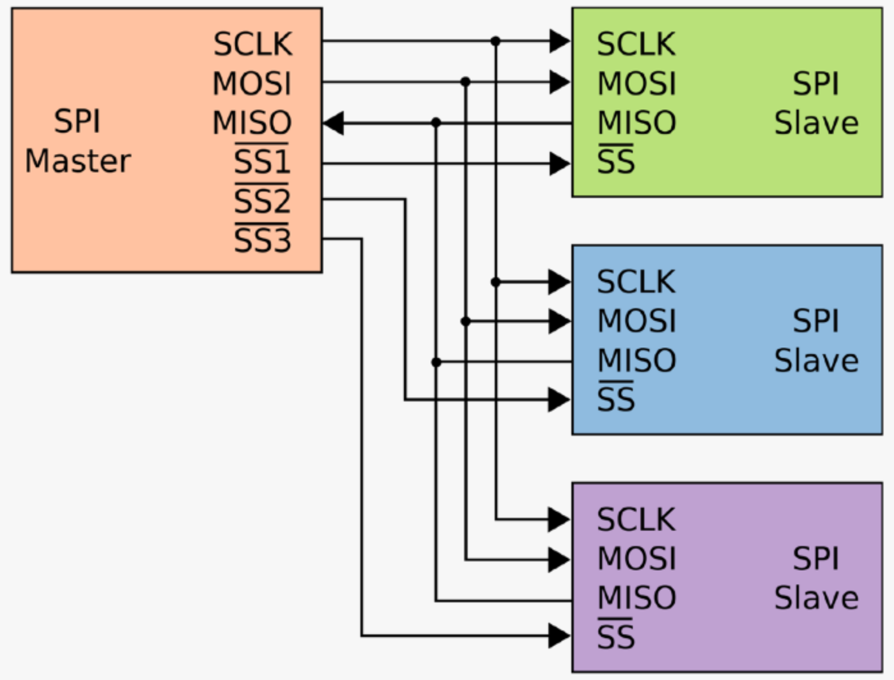


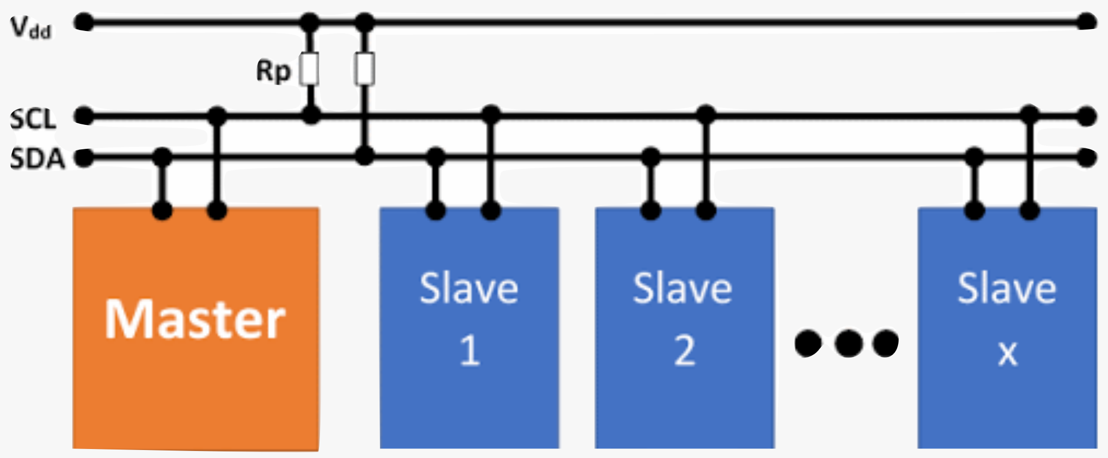
Bus examples (some)



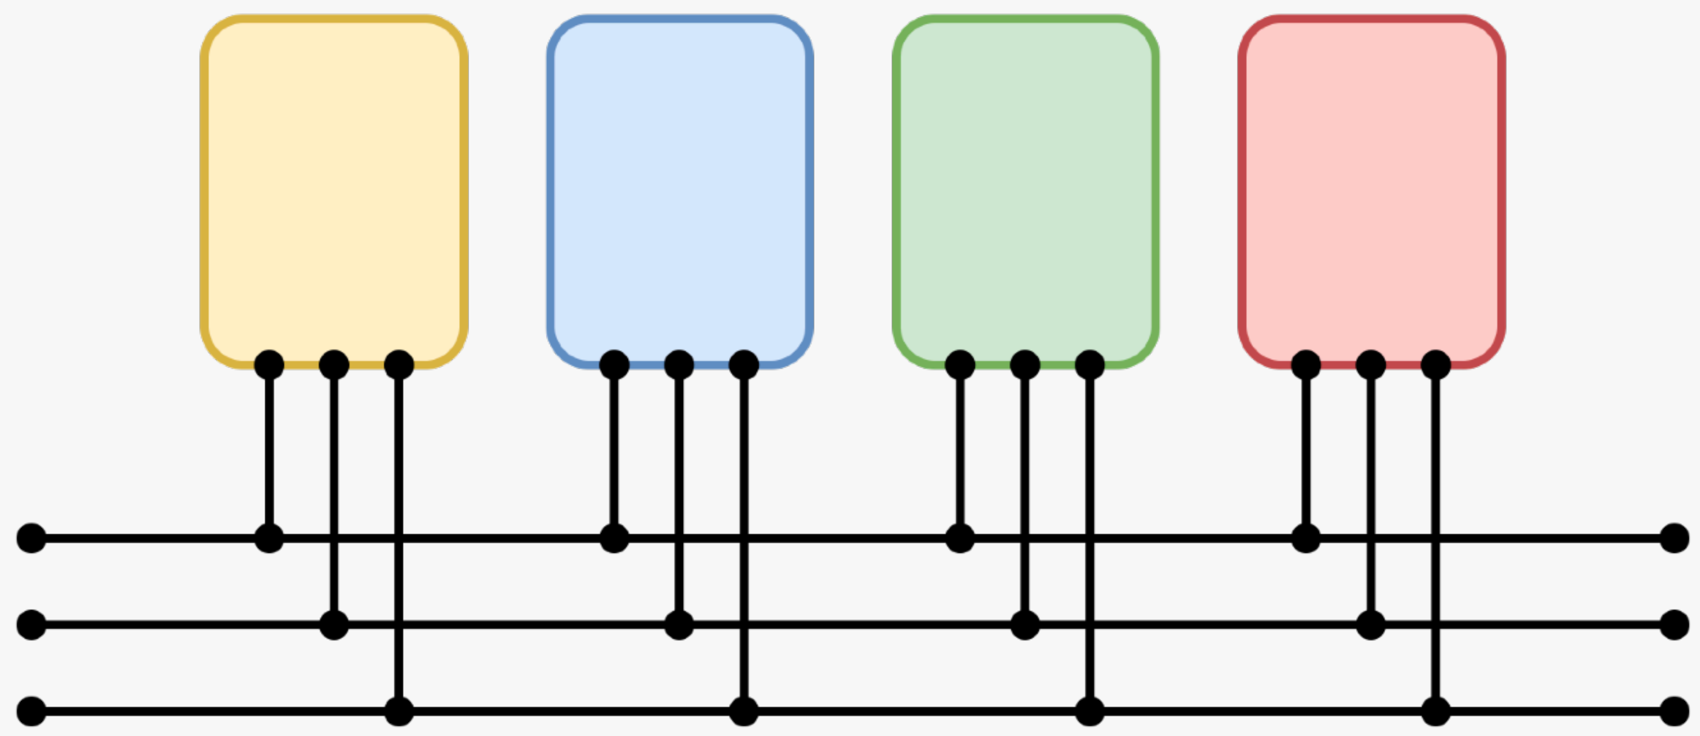
- I2C
- SPI
- UART
- PCI express

- VME
- μTCA
- ATCA





Bus facts



Simple :-)

- Fixed number of lines (bus-width)
- Devices have to follow well defined interfaces
  - Mechanical, electrical, communication, ...

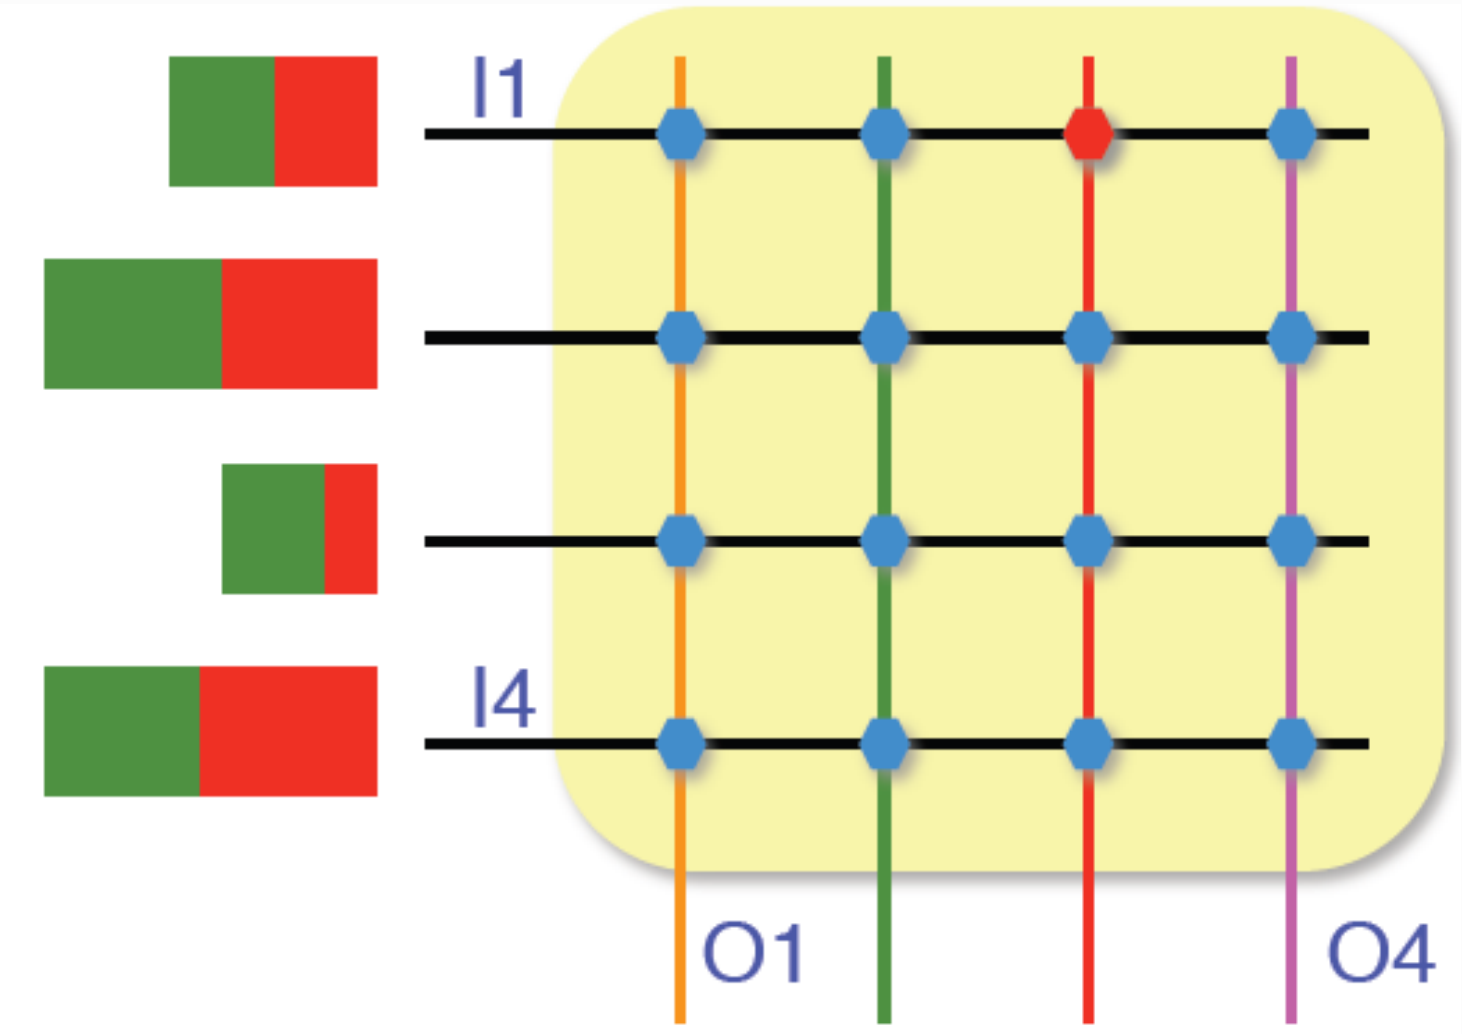
Scalability issues :-(

- Bus bandwidth is shared among all the devices
- Maximum bus width is limited
- Maximum number of devices depends on bus length
- Maximum bus frequency is inversely proportional to the bus length
- On the long term, second order “effects” may limit the scalability of your system

Bus facts

Some second order “effects”

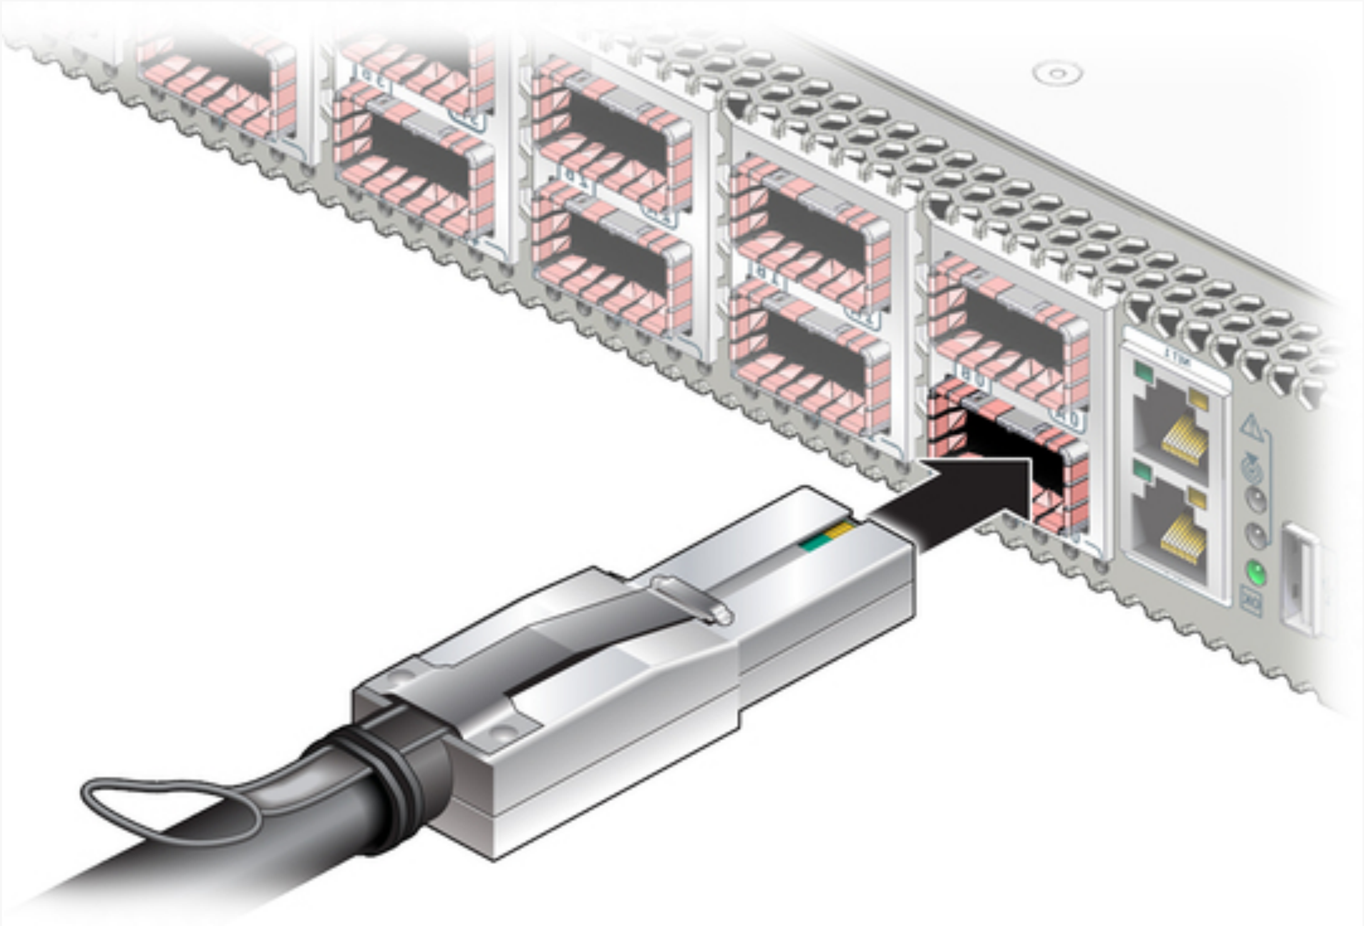
Networks



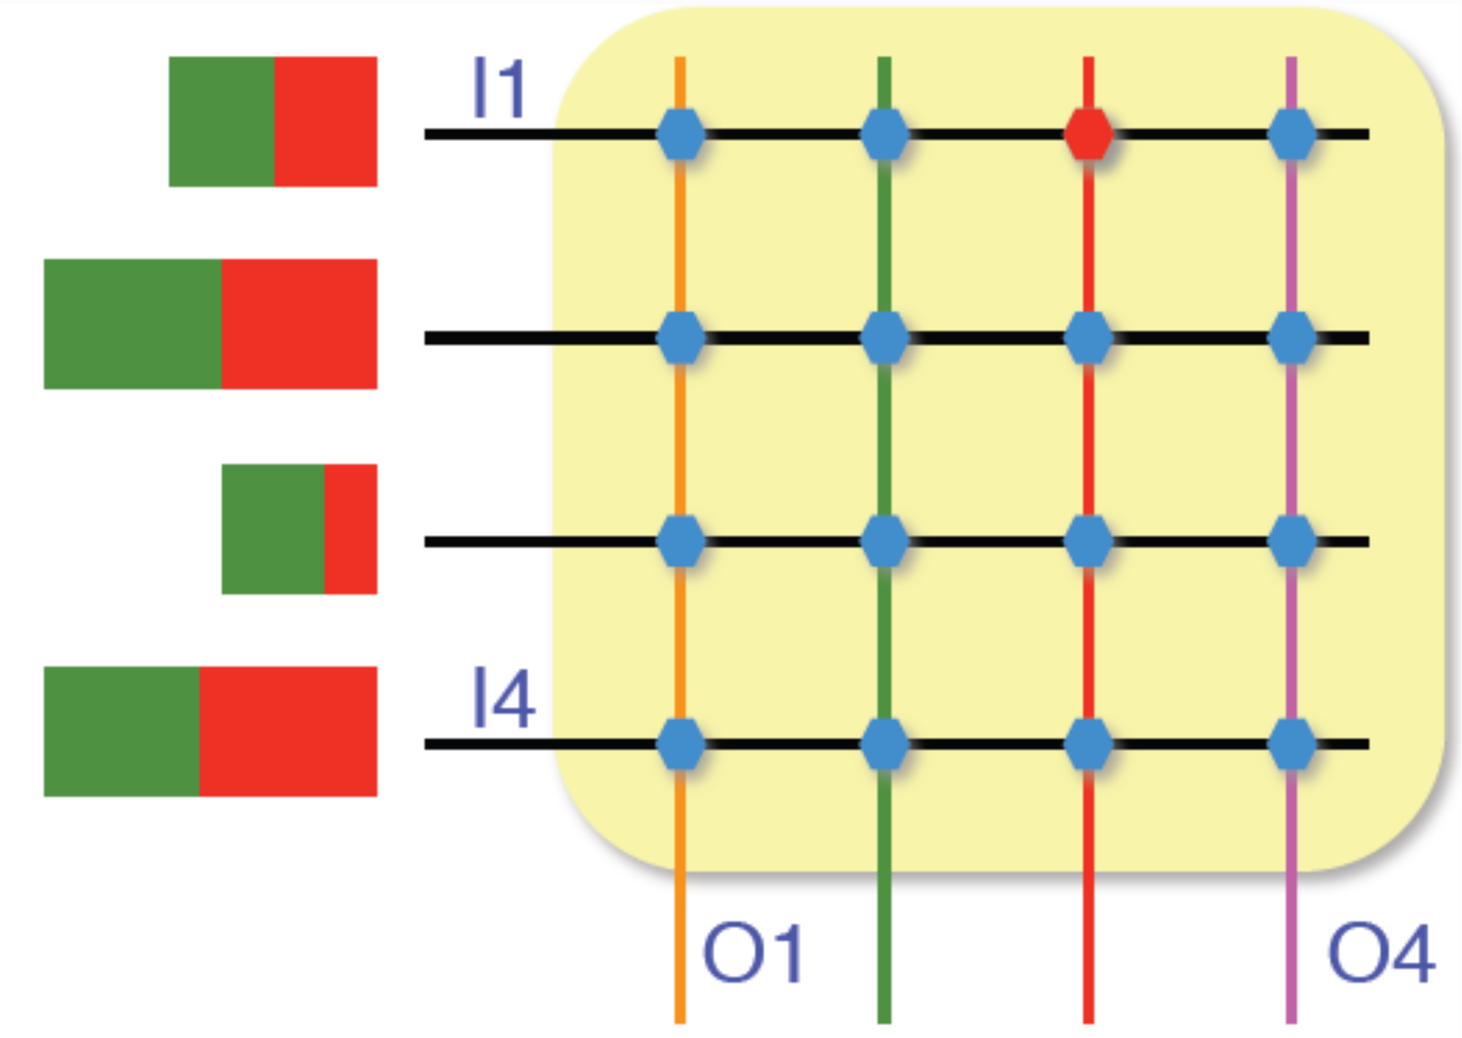
All devices are **equal (peers)**

- They **communicate directly** with each other via messages
  - No arbitration
  - Bandwidth guaranteed
- Not just copper: optical, wireless

Eg: Telephone, Ethernet, Infiniband, …



Networks



In switched networks, **switches** move messages between sources and destinations

- Finds the right path between endpoints

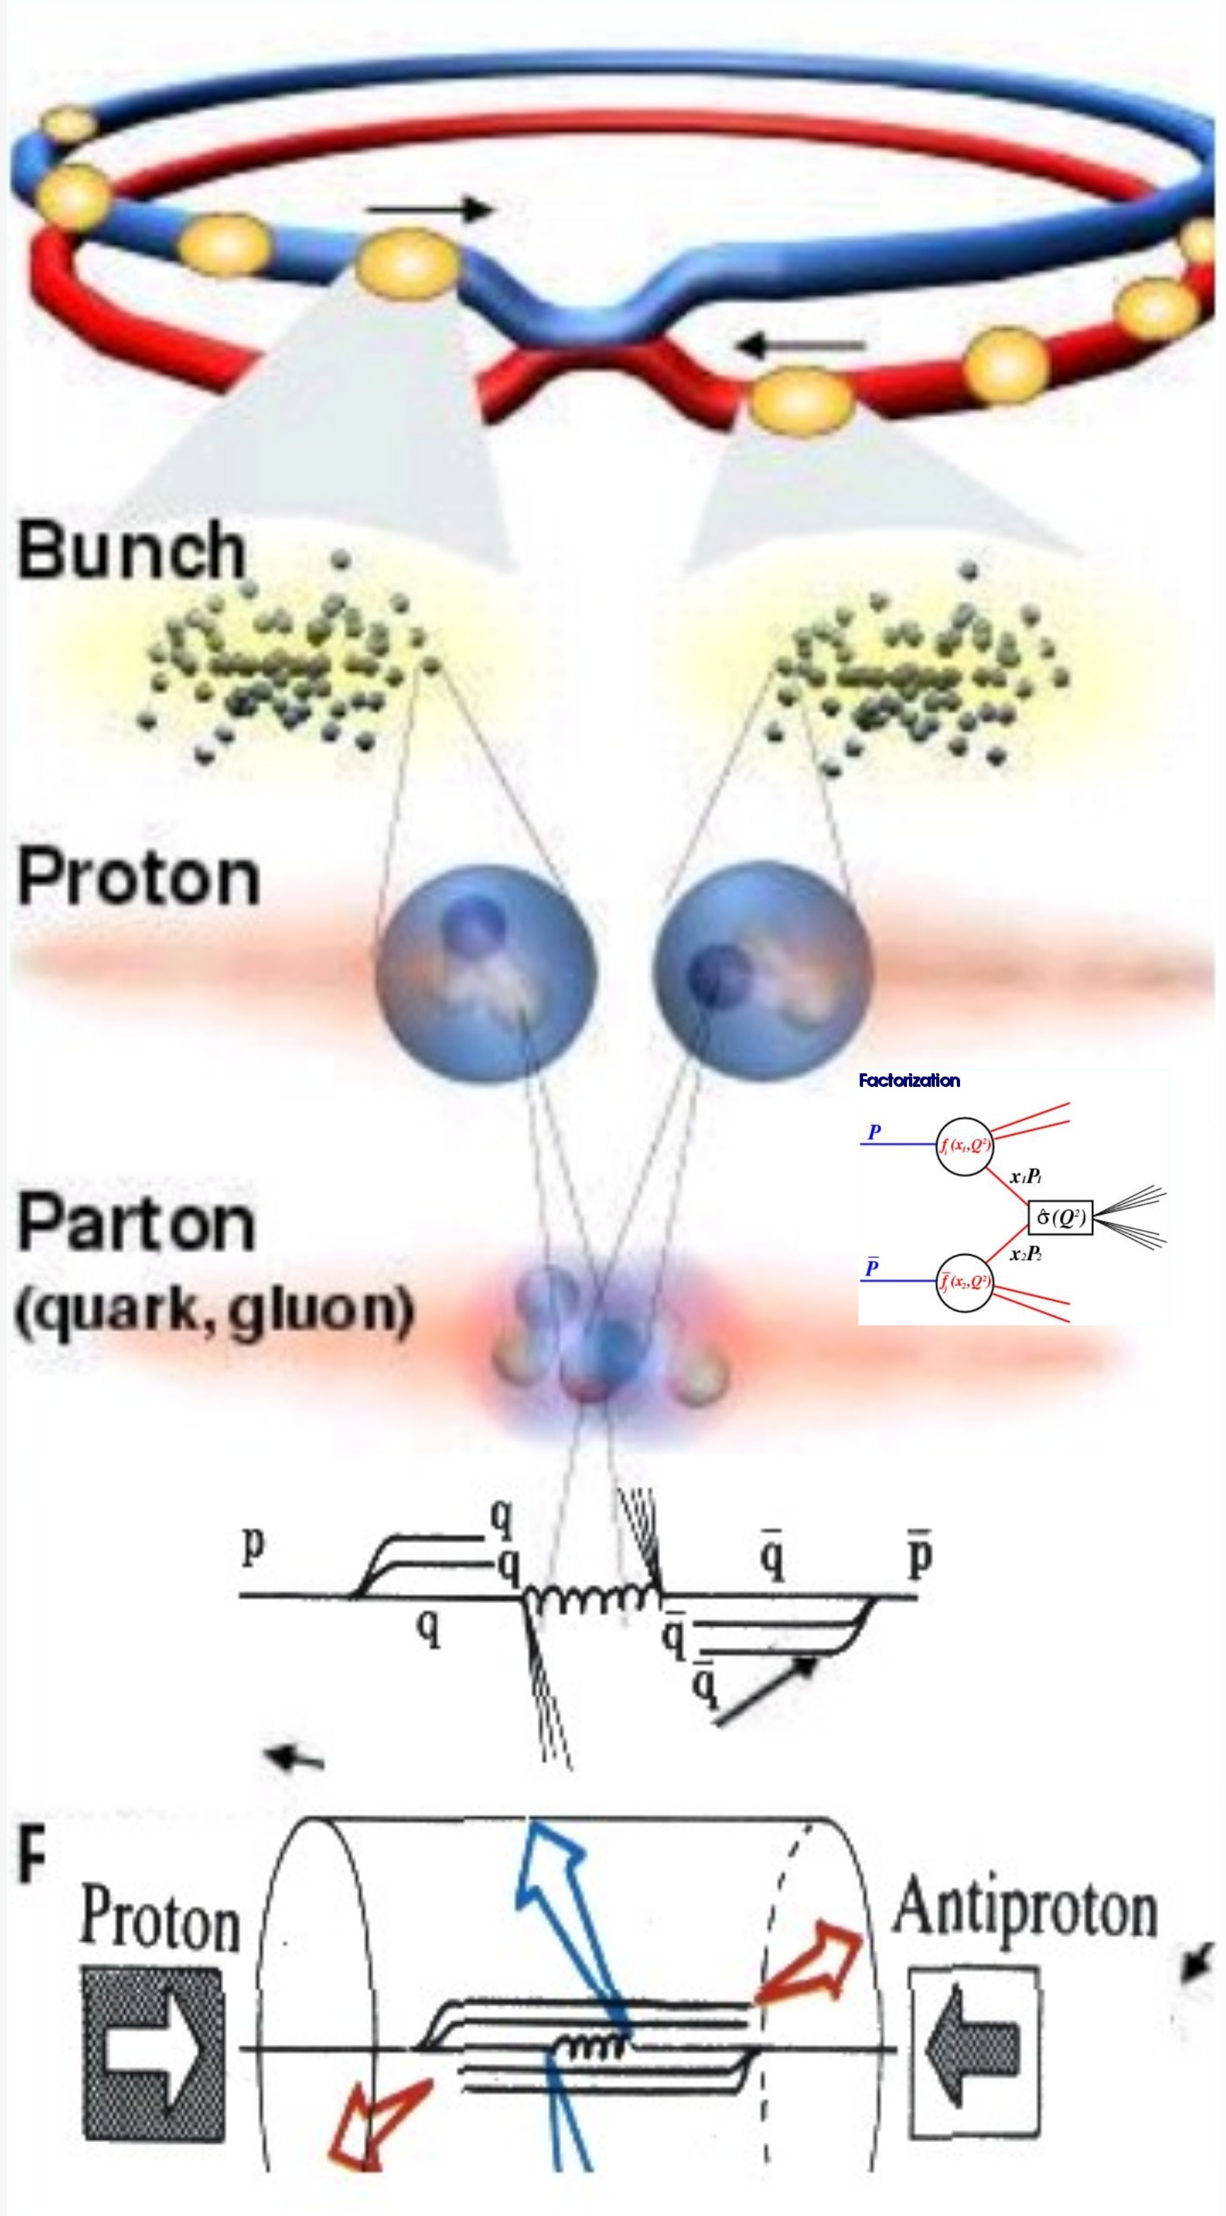
How **congestions** (two messages with the same destination at the same time) are handled?

- The key is ….

Networks

Cable management is still a thing.

LHC and its products



2835×2835 bunches in the LHC ring

10^{11} protons / bunch

≤30 pp collisions per bunch crossing (BC)

N parton-parton collisions / pp collision

Complex final-states in every parton-parton collision.

Design parameters

E_{cms} = 14 TeV
L =10^{34} /cm^2 s
BC clock = 40 MHz

$$R = \sigma_{in} \times L$$

Interesting processes **extremely rare**, high Luminosity is essential

- **Close collisions in space and time**
  - Large proton bunches (1.5x10^{11})
  - Fixed frequency: 40MHz (1/25ns)

Protons are **composite particles**

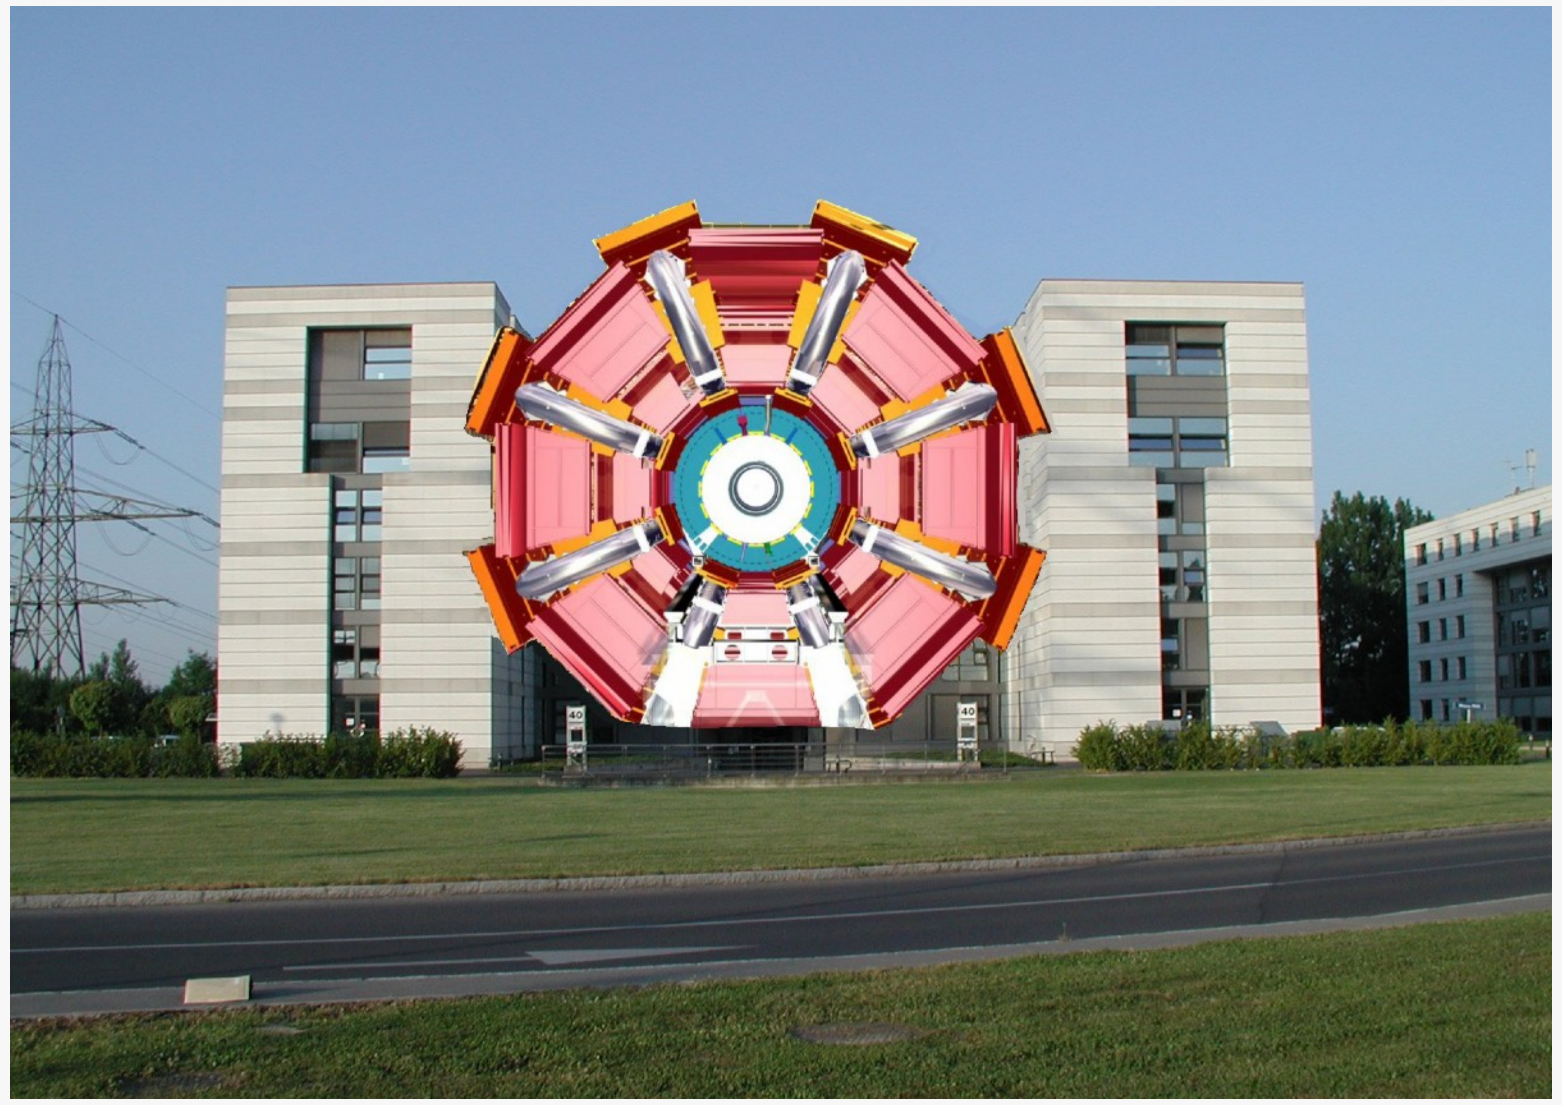
- abundant low energy interactions

Few rare high-E events overwhelmed in abundant low-E environment

LHC Detectors Challenges

Huge

- $O(10^6-10^8)$ channels
- ~1 MB event size for pp collisions
  - 50 MB for pb-pb collisions (Alice)
- Need huge number of connections



Fast and slow detectors

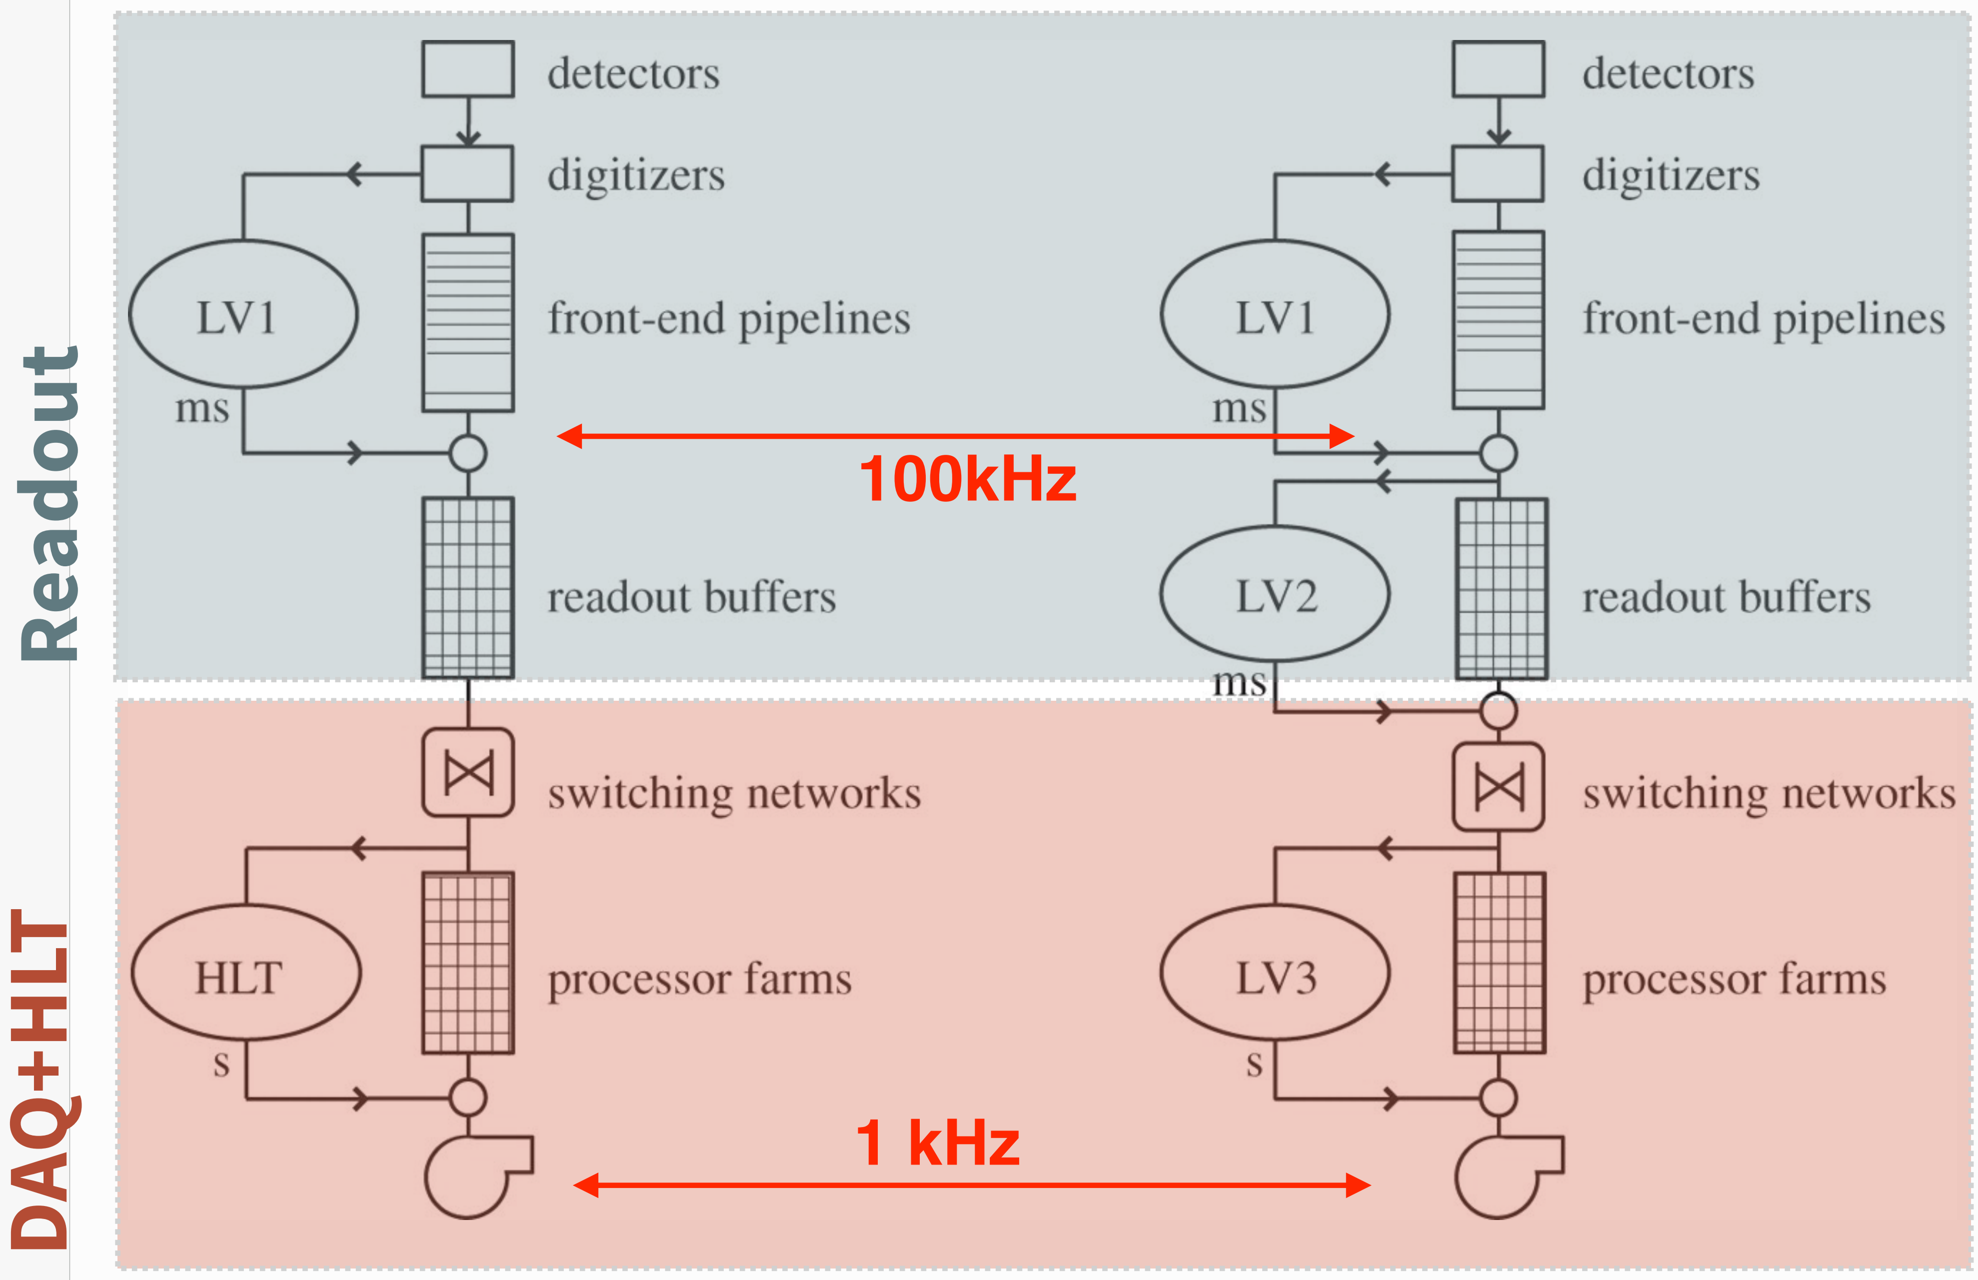
- Some detectors readout requires >25 ns and integrate more than one bunch crossing's worth of information
  - e.g. ATLAS LArg readout takes ~400 ns

Online, what is lost is lost forever

- Need to monitor selection - need very good control over all conditions

HLT/DAQ requirements

- Robustness and redundancy
- Scalability to adapt to Luminosity, detector evolving conditions
- Flexibility (> 10-years lifetime)
- Based on commercial products
- Limited cost



ATLAS/CMS Example

- 1 MB/event at 100 kHz for O(100ms) HLT latency
  - Network: 1 MB*100 kHz = 100 GB/s
  - HLT farm: 100 kHz*100 ms = O(10^4) CPU cores
- Intermediate steps (level-2) to reduce resources, at cost of complexity (at ms scale)

Prefer COTS hardware: PCs (linux based), Ethernet protocols, standard LAN, configurable devices

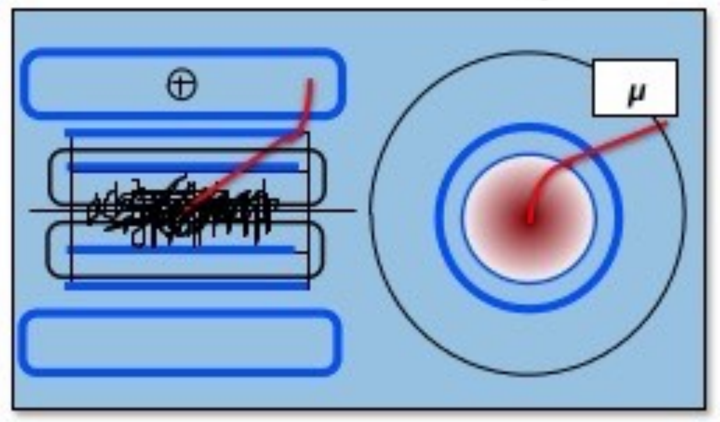
See S.Cittolin, DOI: 10.1098/rsta.2011.0464

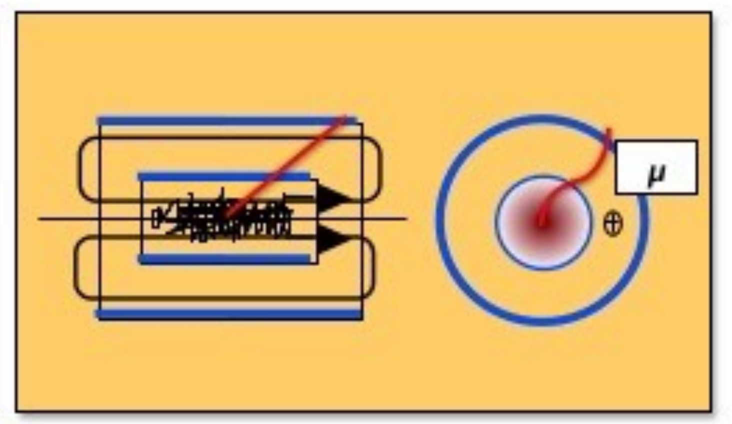
ATLAS & CMS design principles

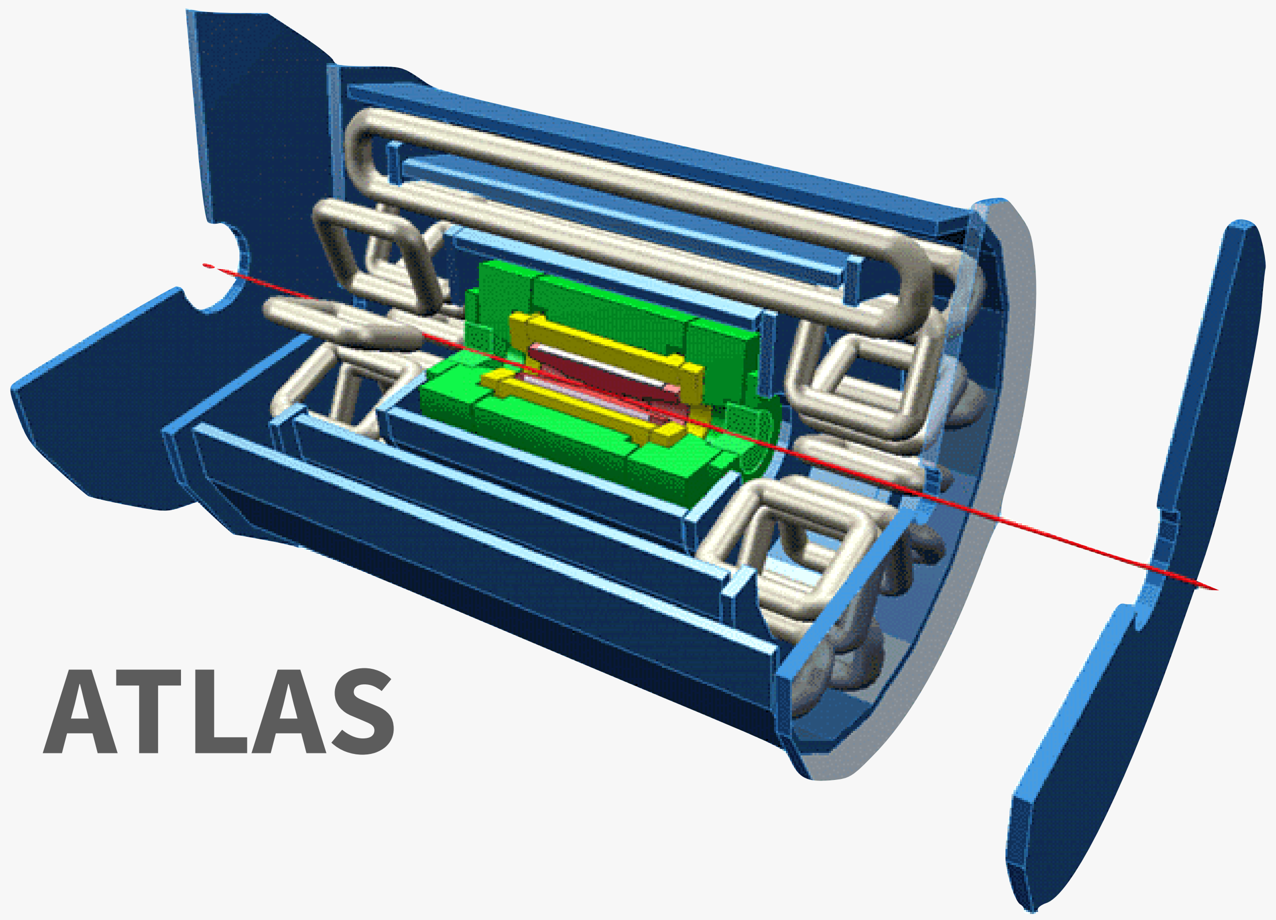
Same physics program

Different magnetic field structure

- **ATLAS**: 2 T solenoid + Toroids
- **CMS**: strong 4 T solenoid

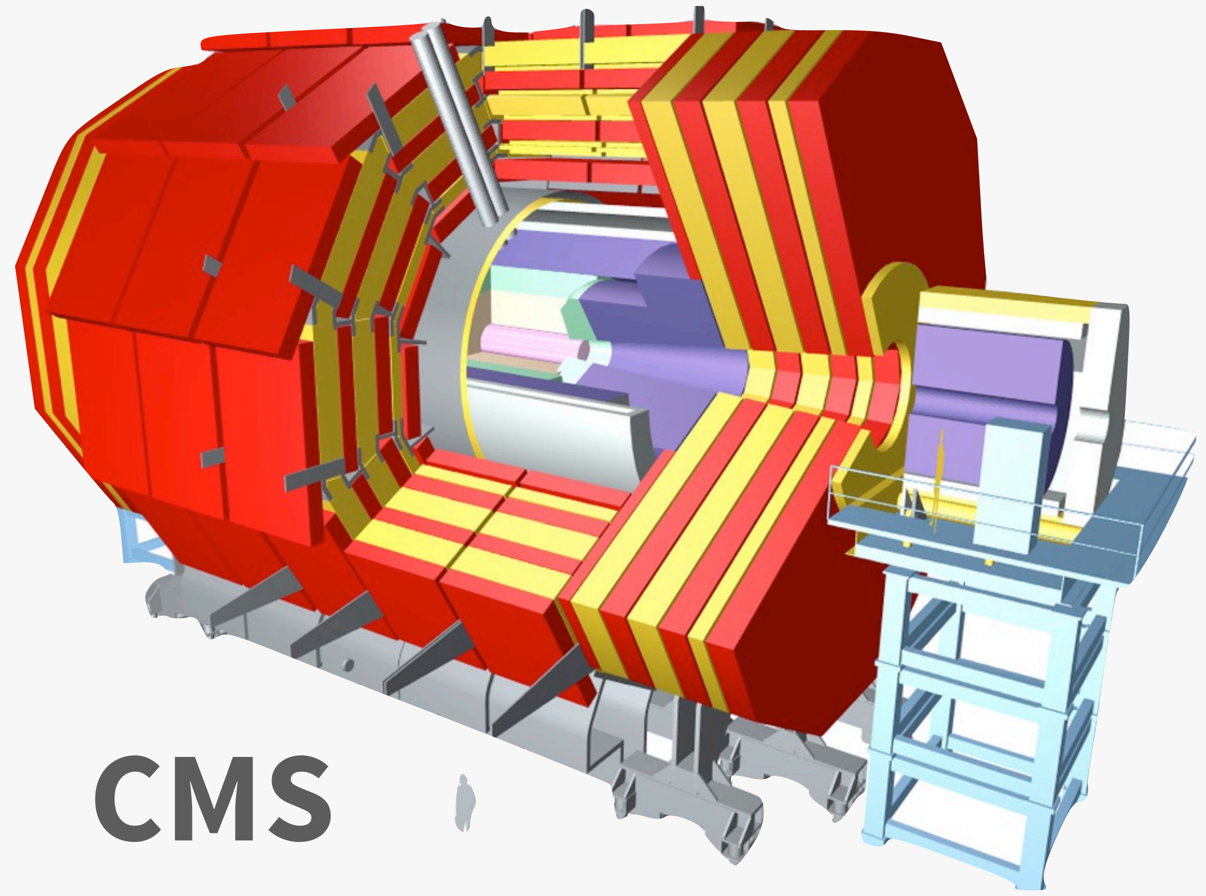






Different DAQ architecture

- **ATLAS**: minimise data flow bandwidth
  with multiple levels and regional readout
- **CMS**: large bandwidth, invest on commercial technologies
  for processing and communication



Same data rates

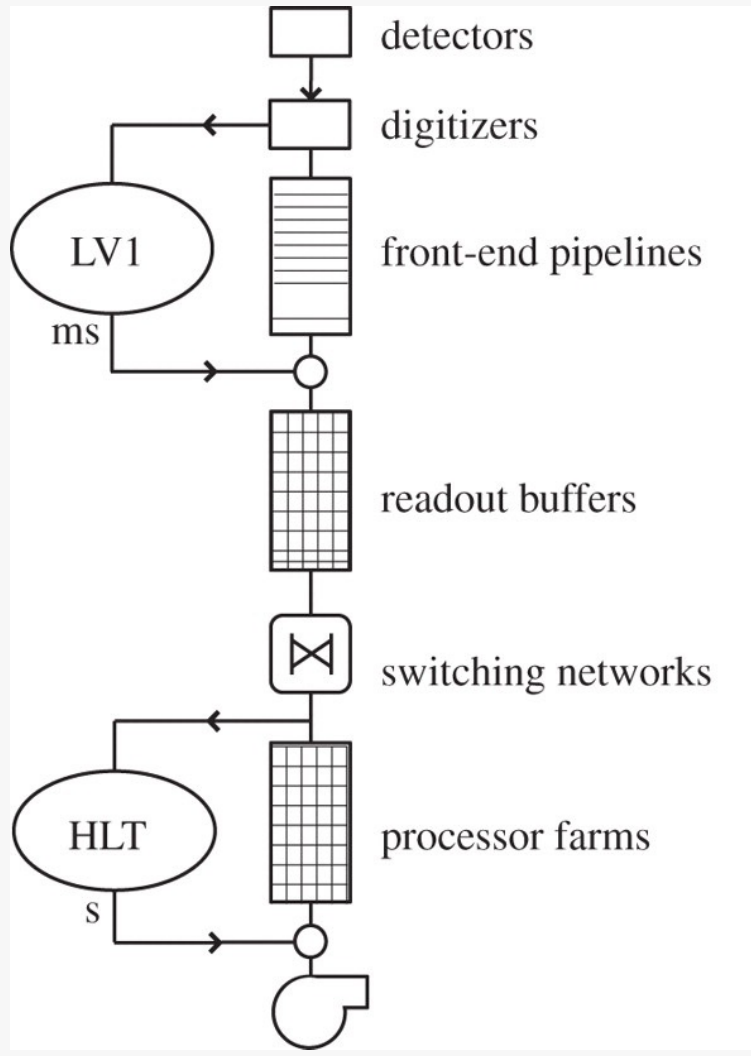
- ~1 MB * 100 kHz = ~100 GB/s readout network

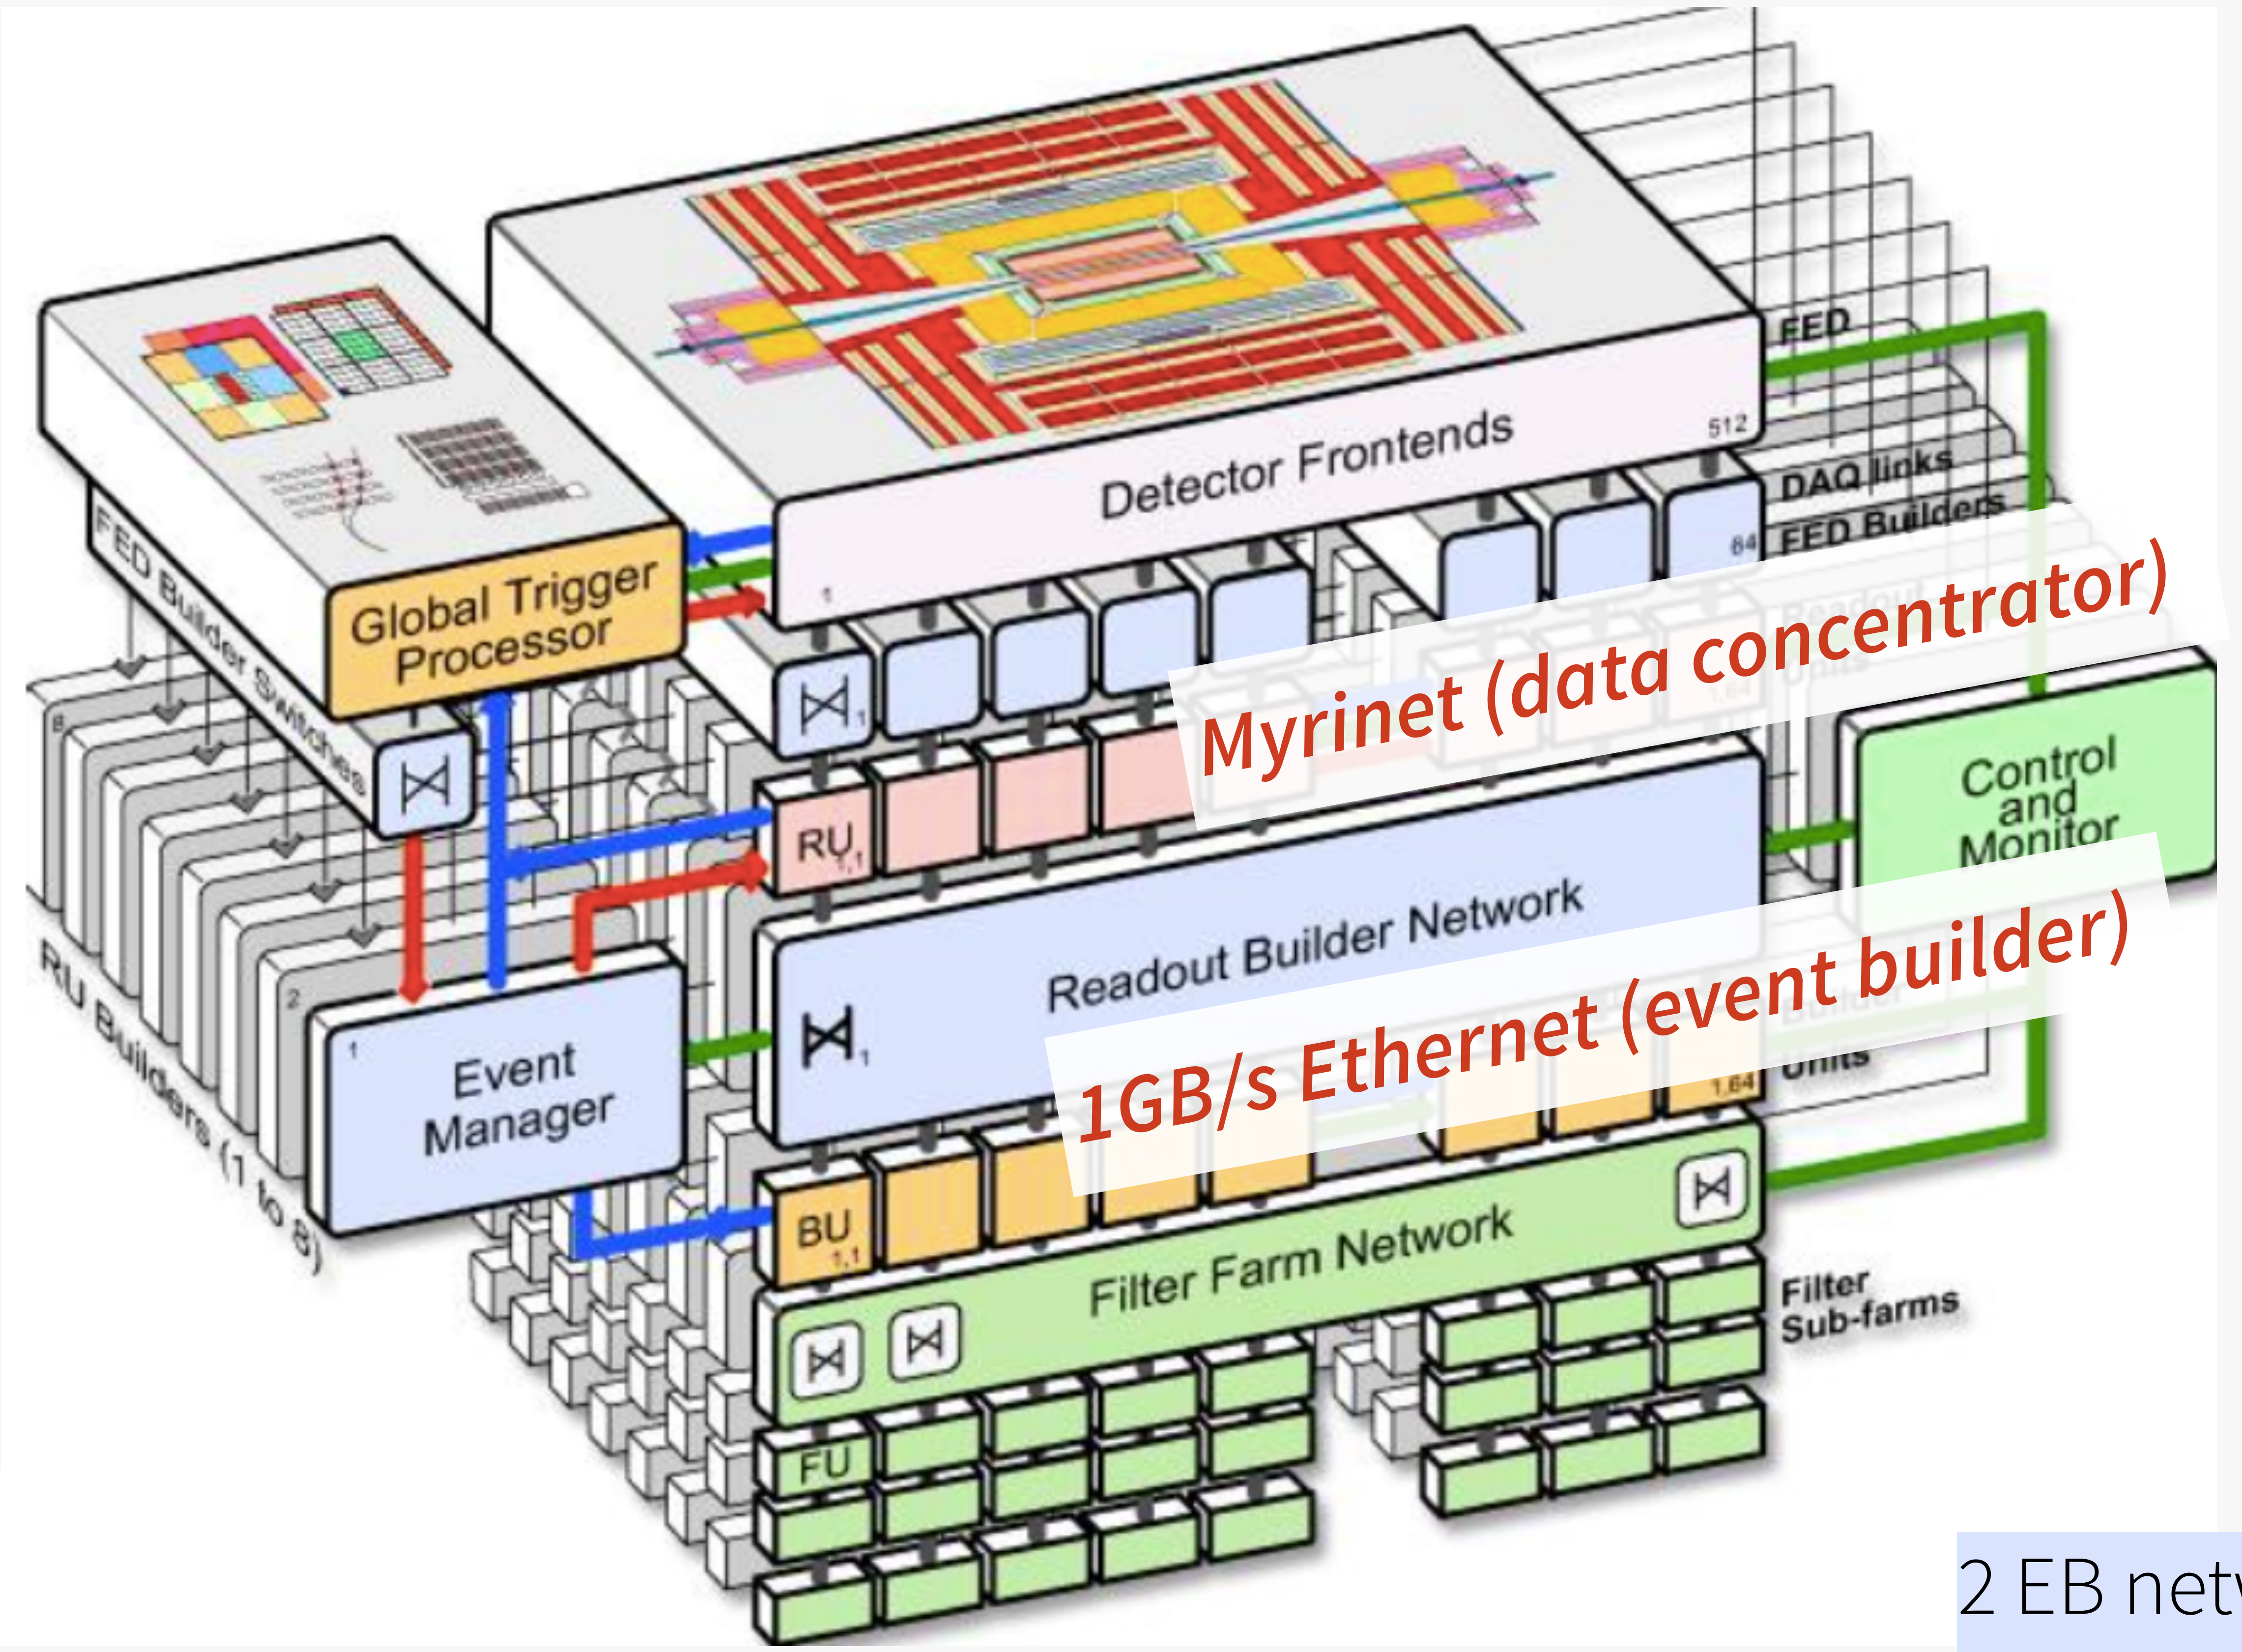
CMS: 2-stage Event building

CMS DAQ-1

Run-1 (as from TDR, 2002)

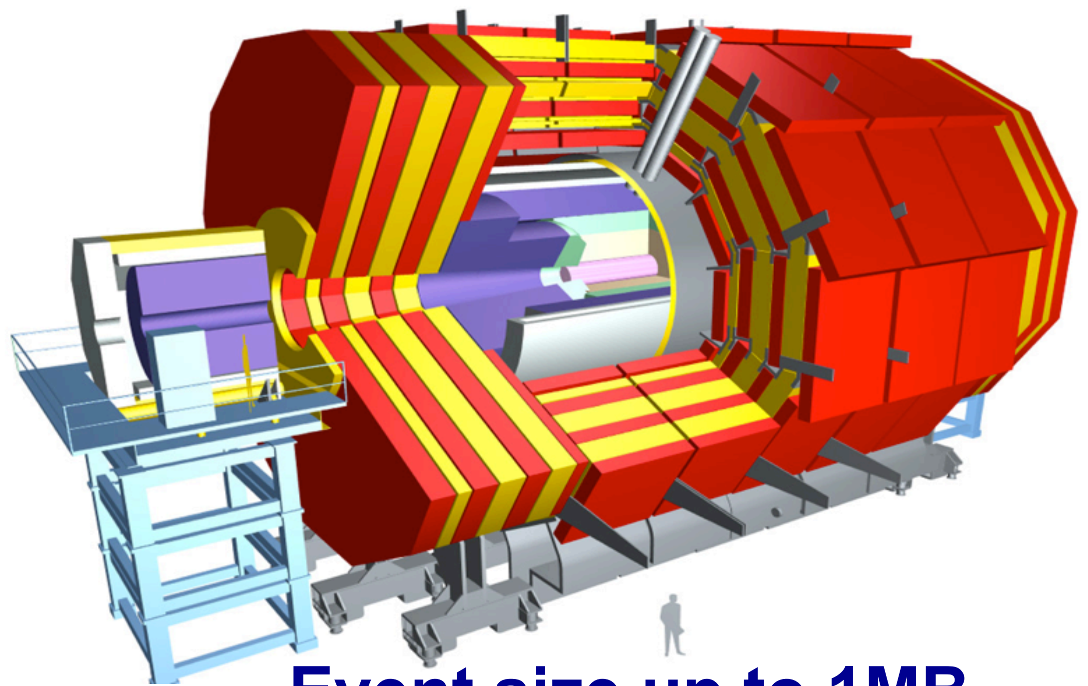
- Myrinet + 1GBEthernet
- 1-stage building: 1200 cores (2C)
- HLT: ~13,000 cores
- 18 TB memory @100kHz:
  ~90ms/event





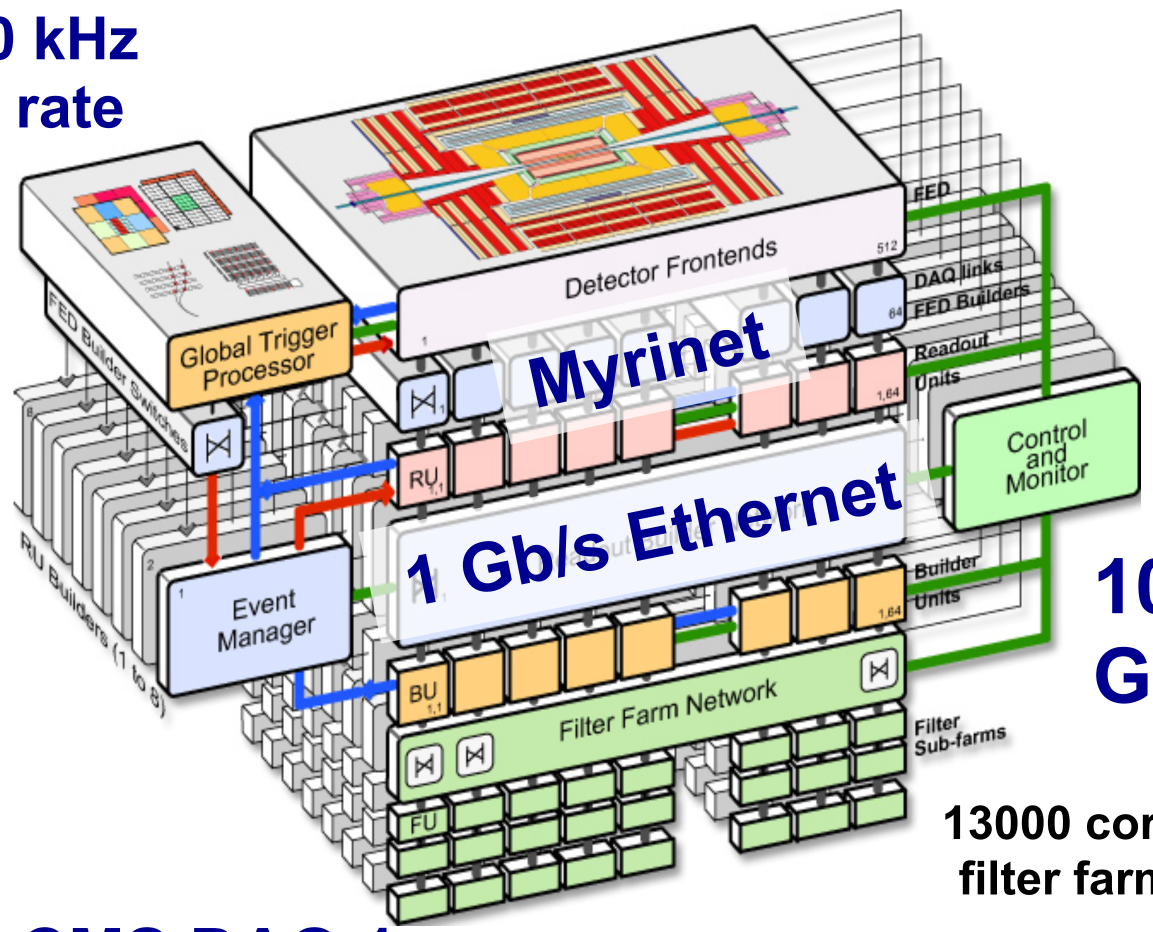
2 EB networks

Filter network



Event size up to 1MB

100 kHz
L1 rate

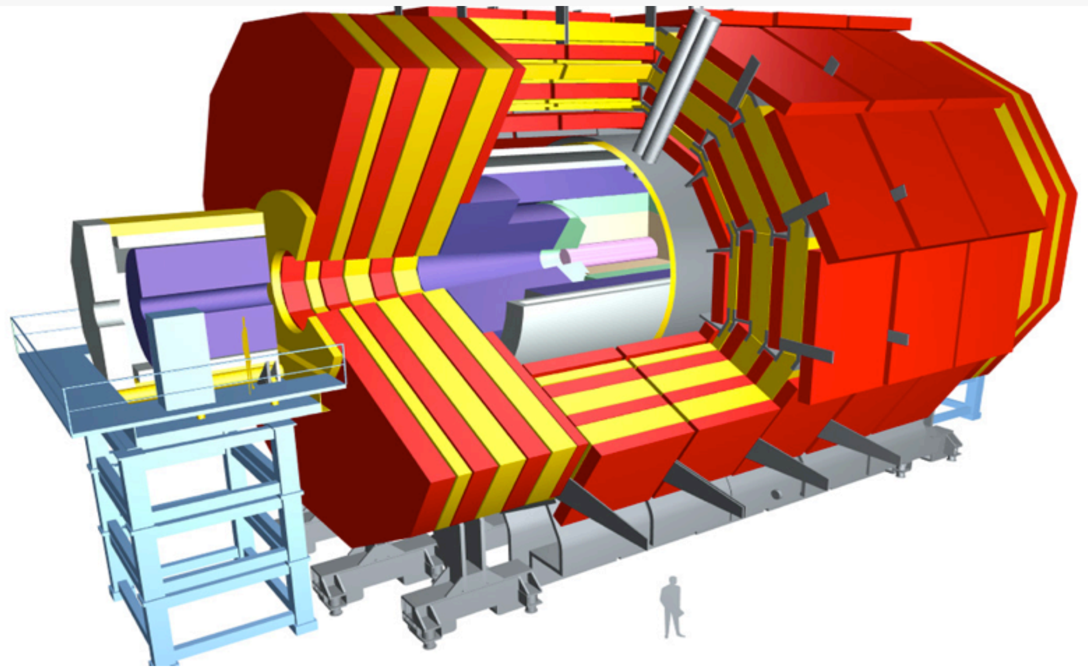


100 GB/s

13000 core
filter farm

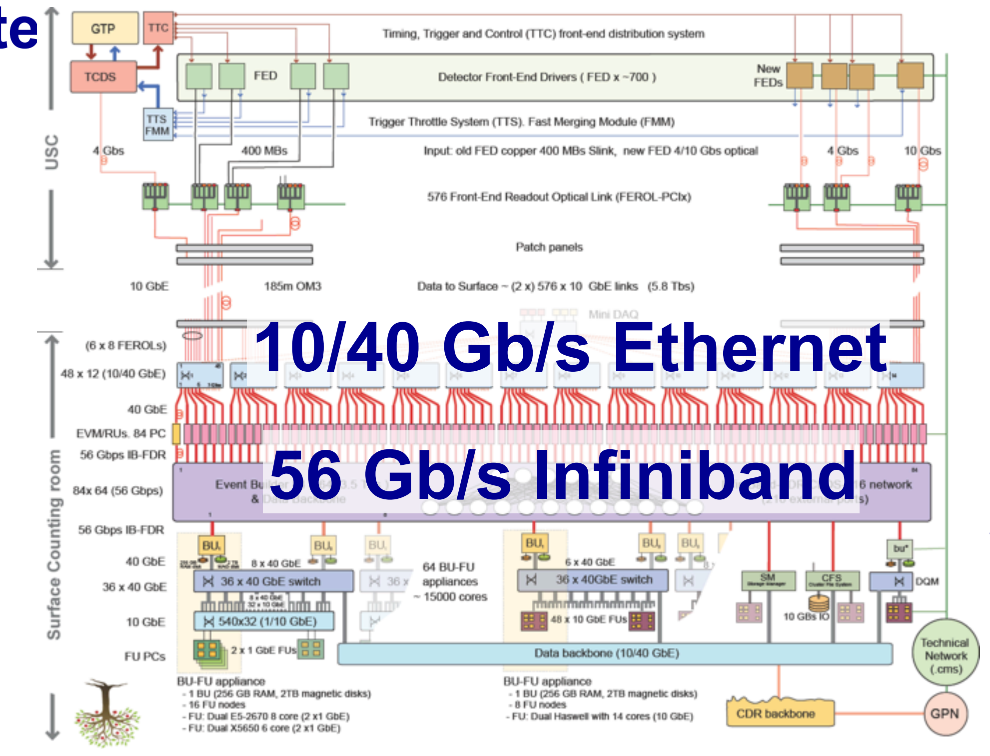
CMS DAQ 1

max. 1.2 GB/s to storage



Event size up to 2MB
(large margin)

100 kHz
L1 rate



200 GB/s

16000+ core
filter farm

CMS DAQ 2

~ 3 GB/s to storage

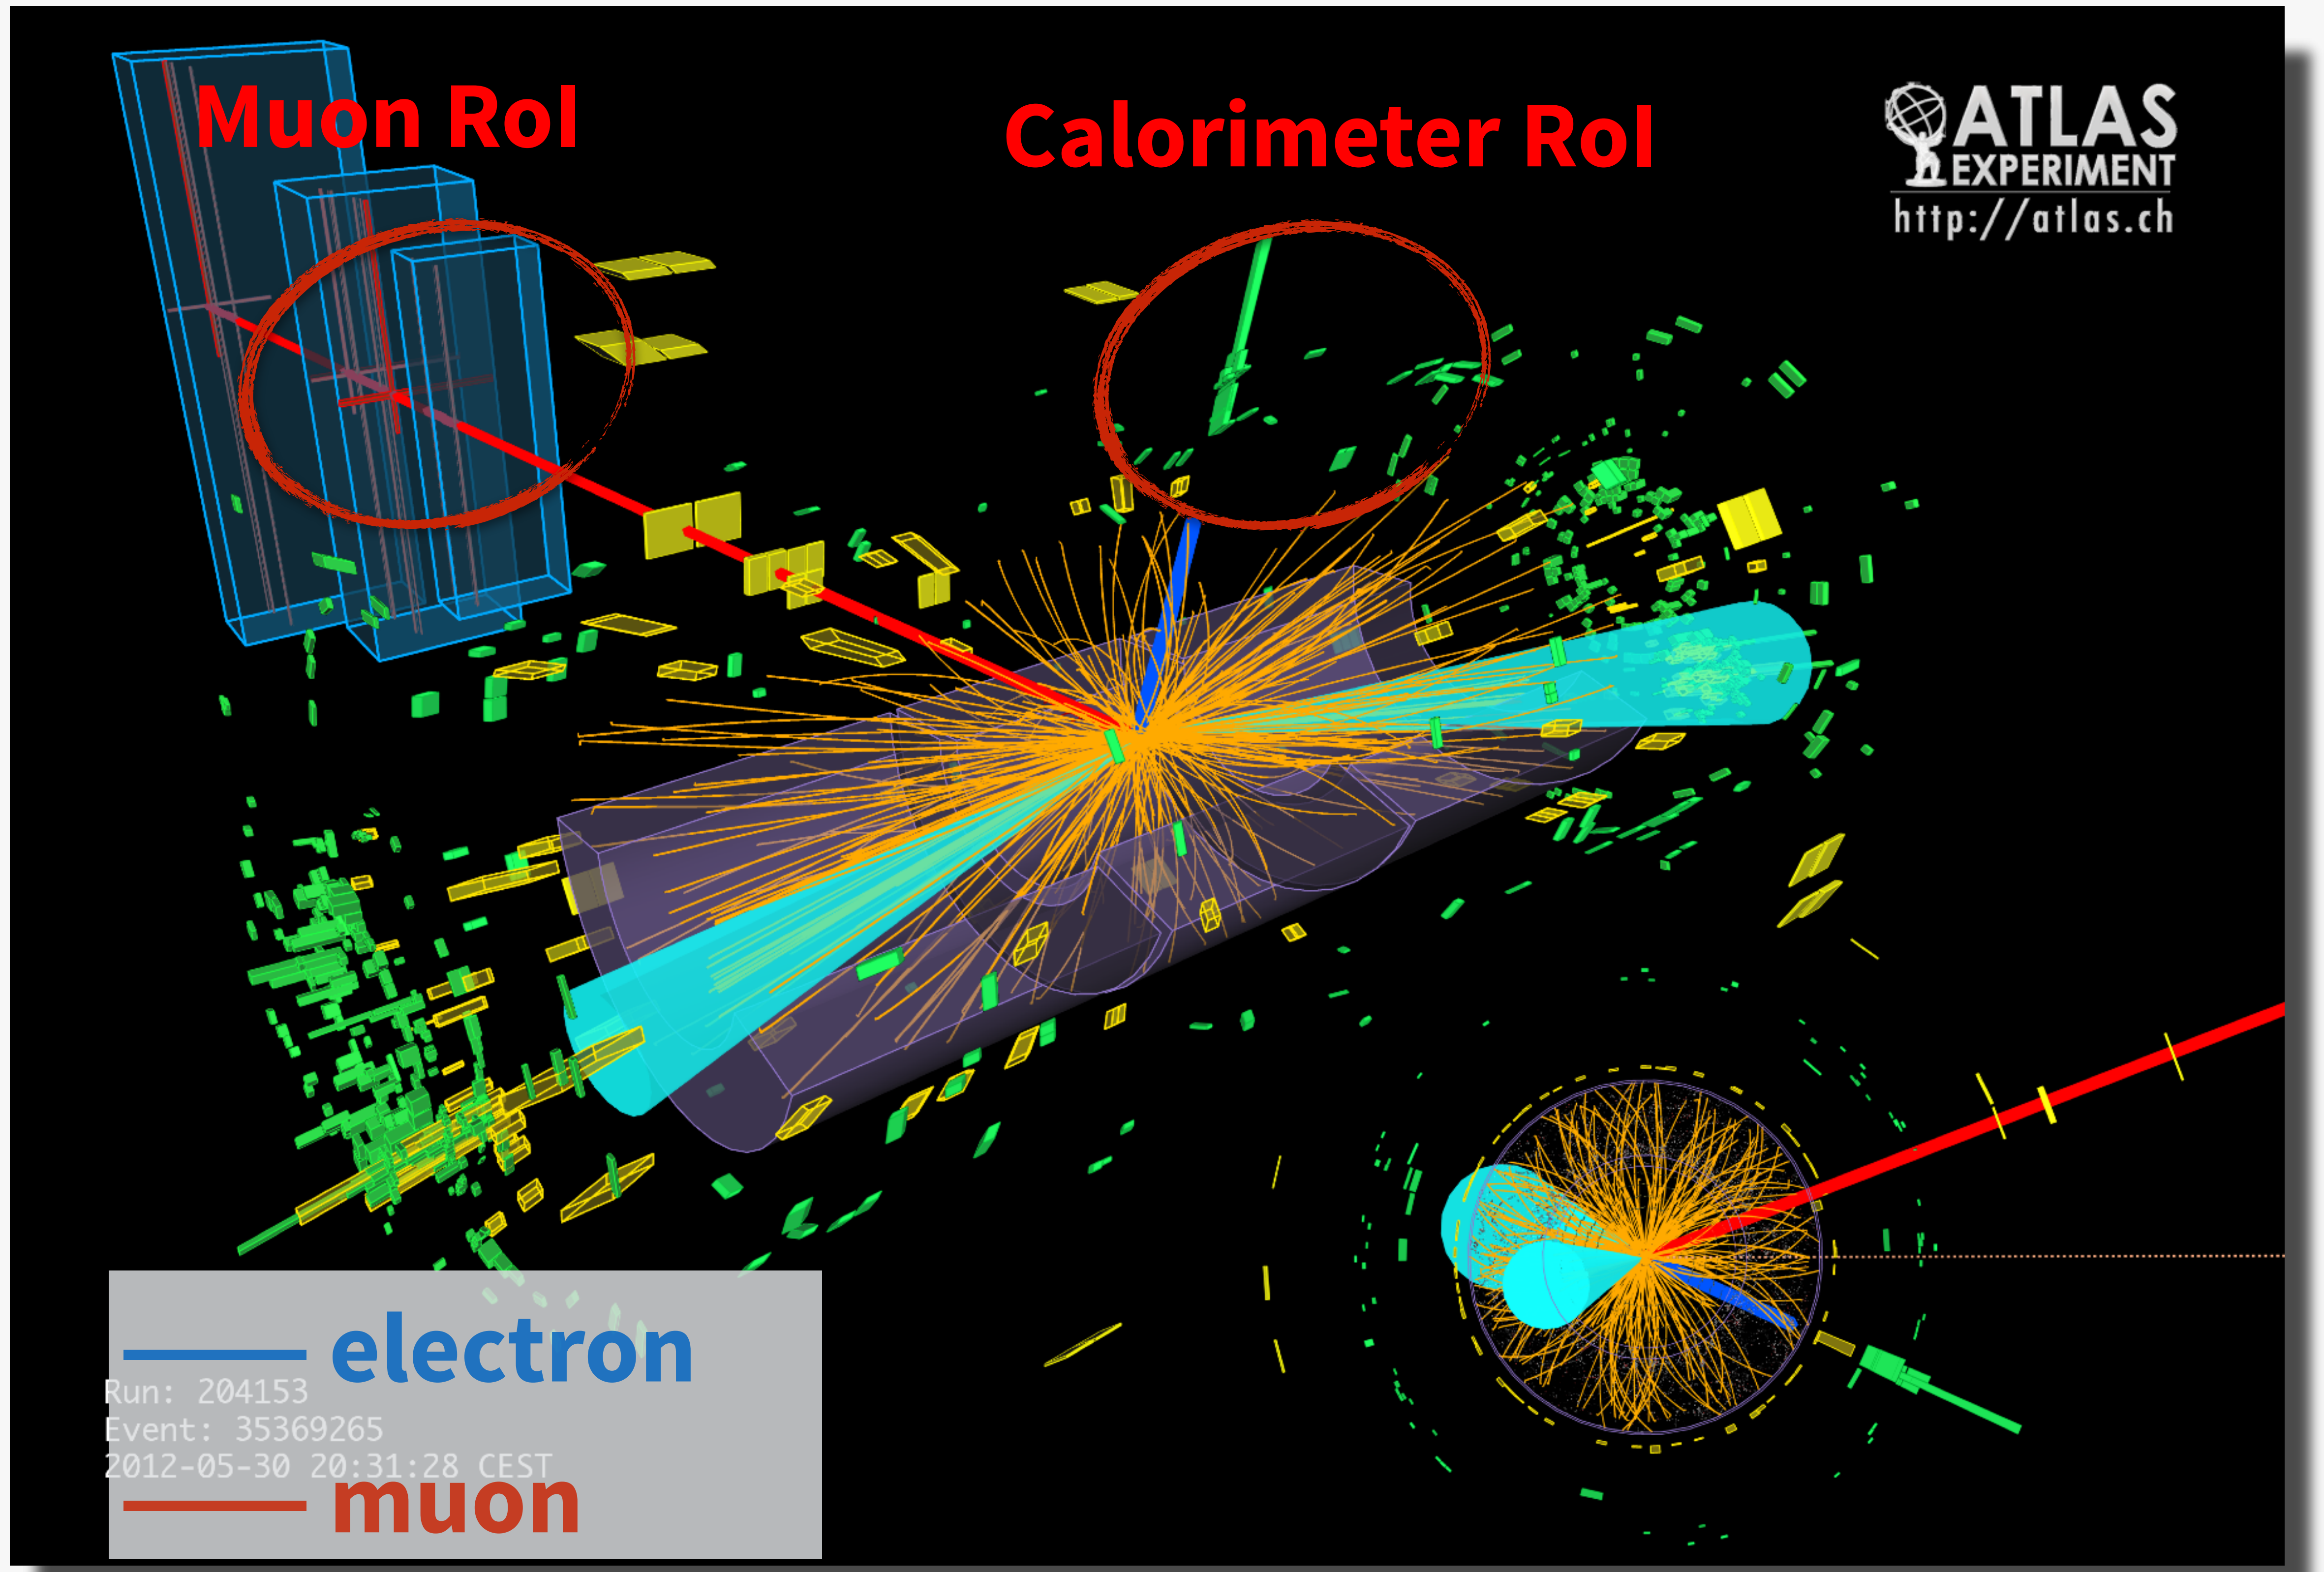
ATLAS: Region of Interest (ROI) dataflow

HLT selections based on regional readout and reconstruction

- seeded by L1 trigger objects (RoI)

Total amount of RoI data is minimal: a few % of the Level-1 throughput

- one order of magnitude smaller readout network
- at the cost of a higher control traffic and reduced scalability



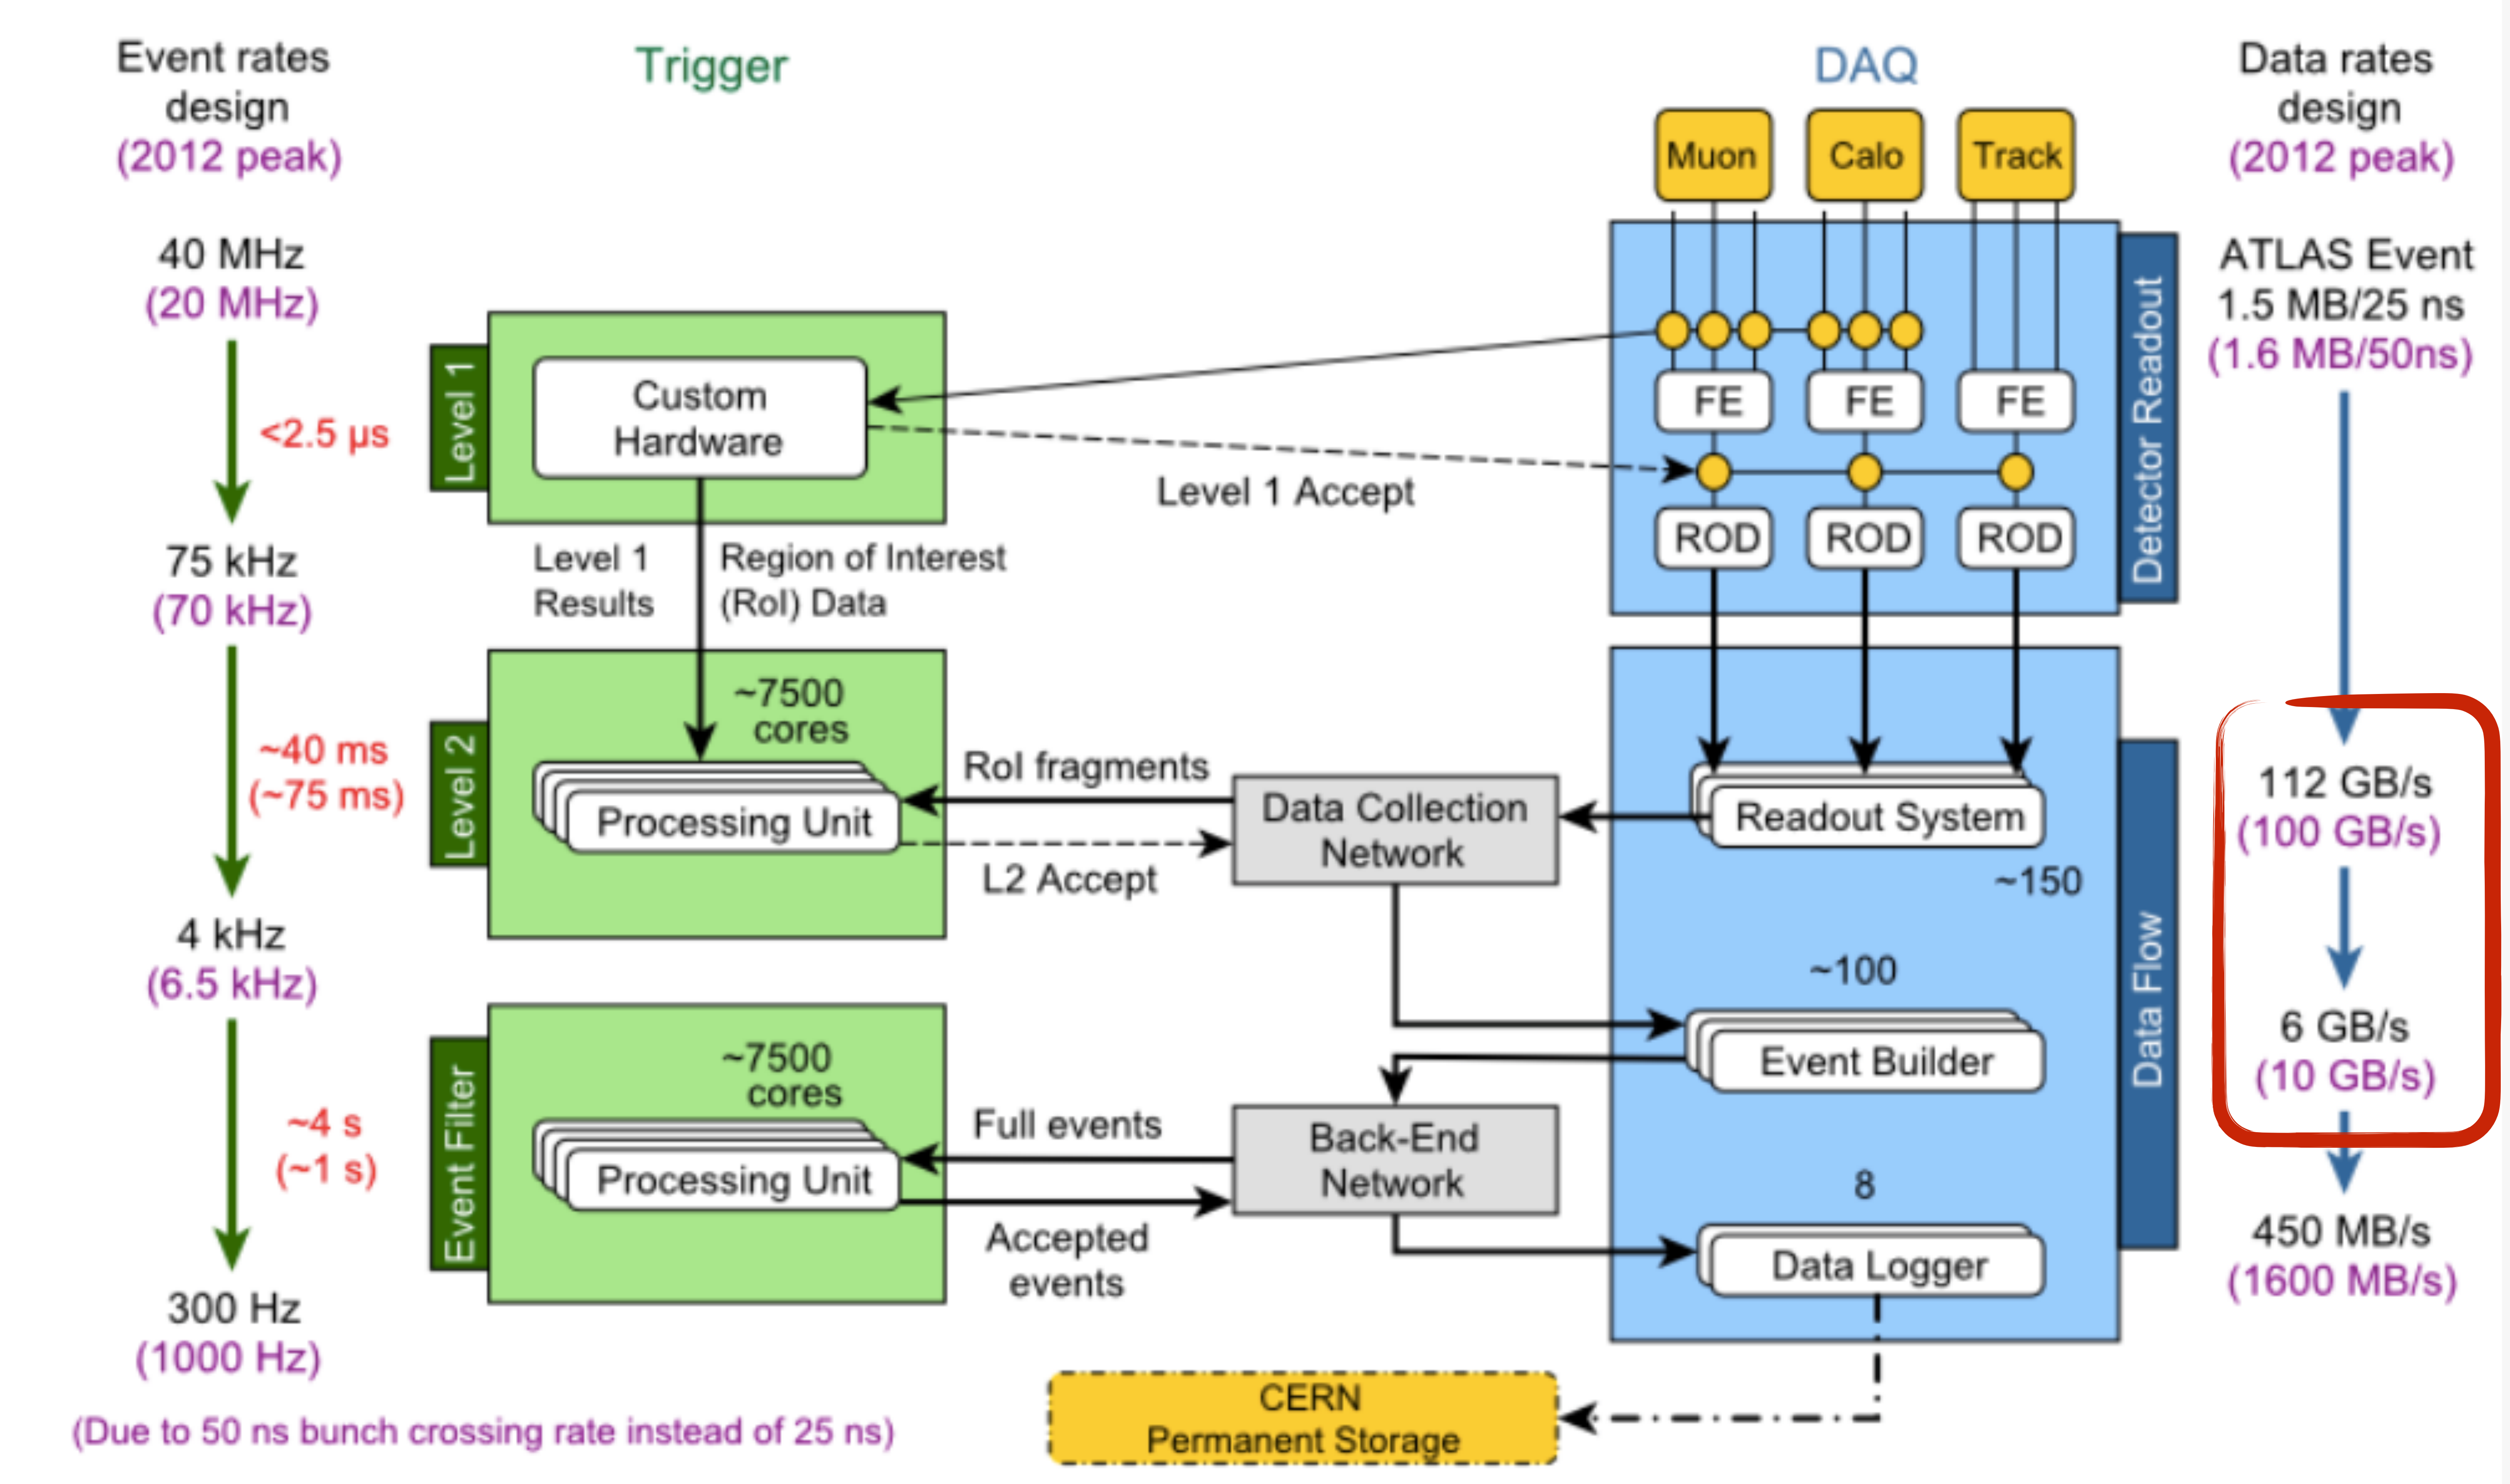
ATLAS: SEEDED reconstruction HLT

RUN 1

Overall network bandwidth: ~10 GB/s

- x10 reduced by regional readout)

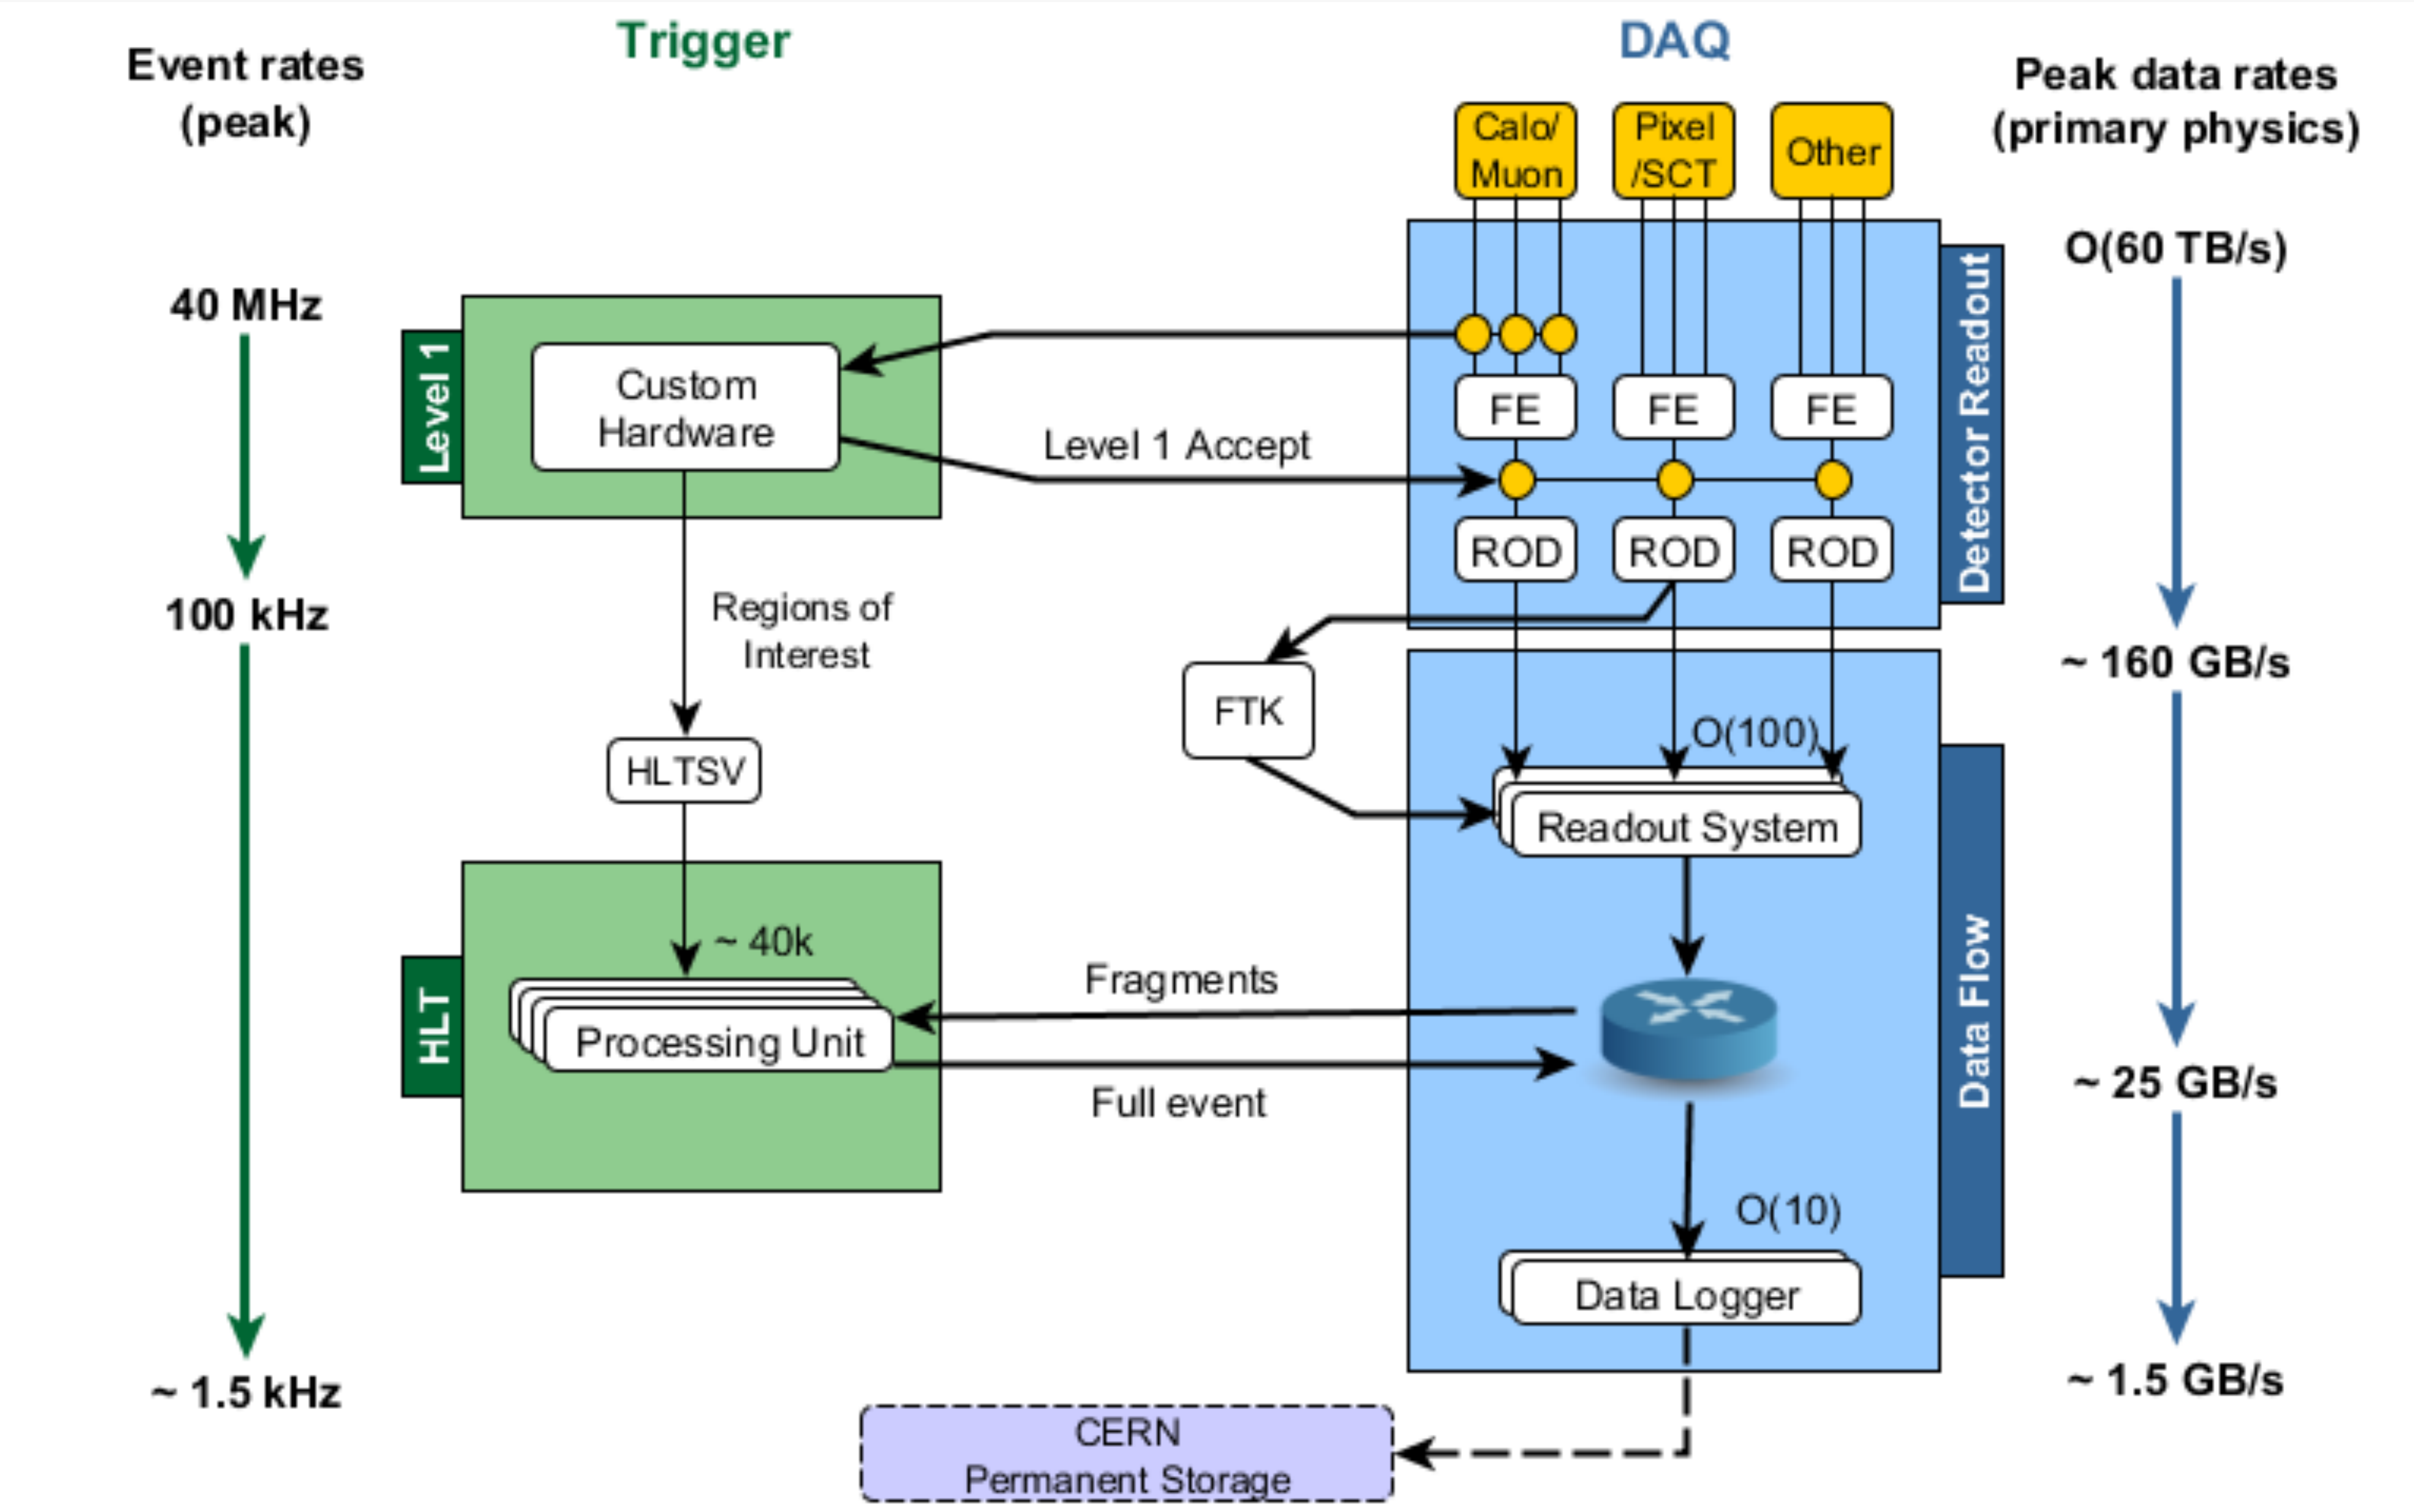
Complex data routing



NEW TDAQ architecture for Run-2

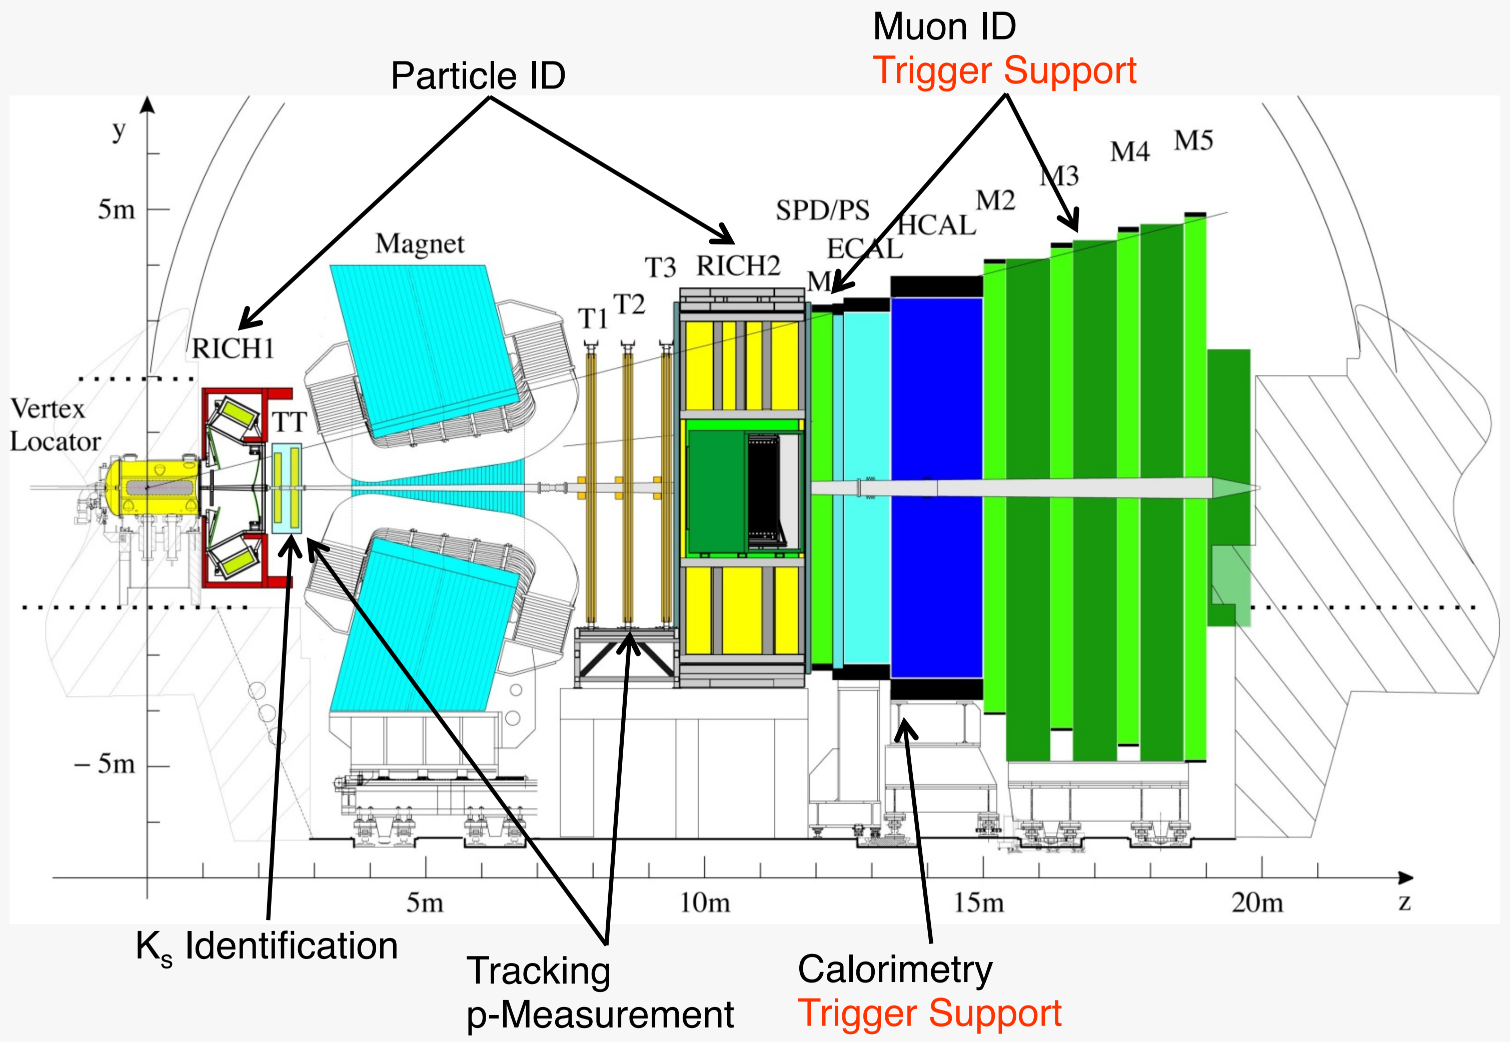
RUN 2

- Increased rates
- Merged L2/HLT
- Increase Readout bandwidth
- Increase HLT rate
- Unified network



LHCb TDAQ Architecture

RUN 2

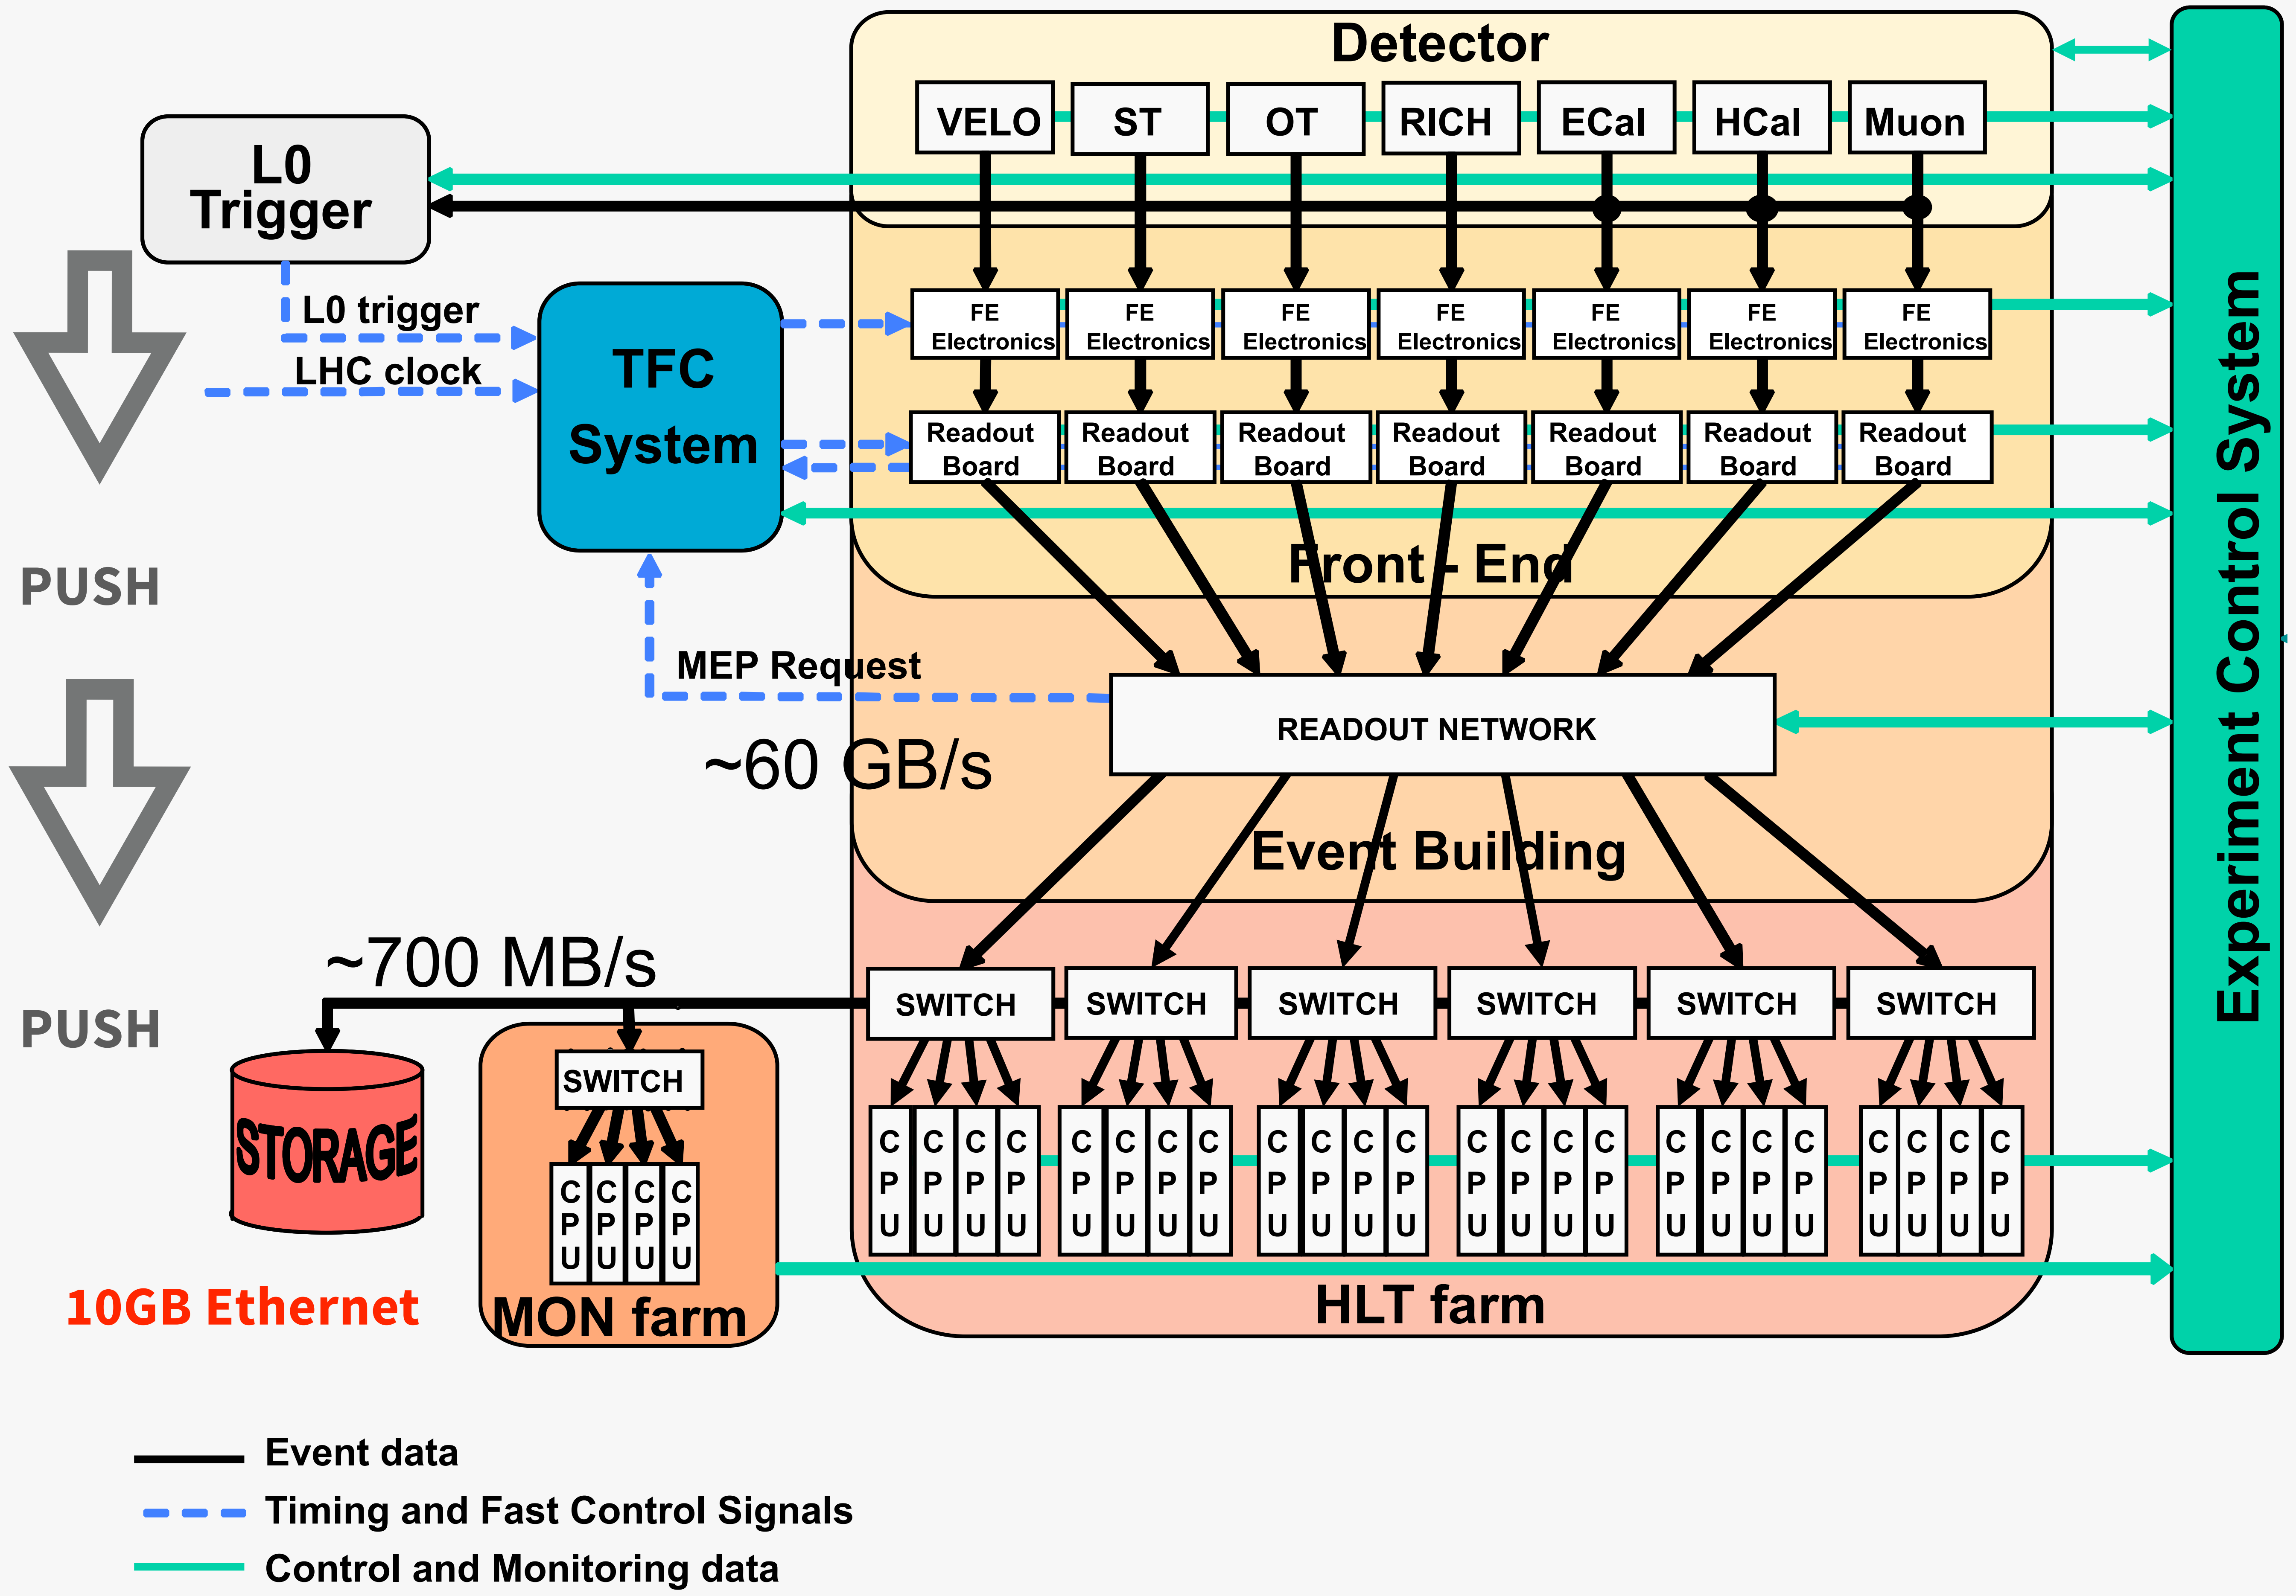


Single forward arm spectrometer → reduced event size

- Average event size 60 kB
- Average rate into farm 1 MHz
- Average rate to tape ~12 kHz

Small event, at high rate

- optimised transmission



No Level-1 Trigger!

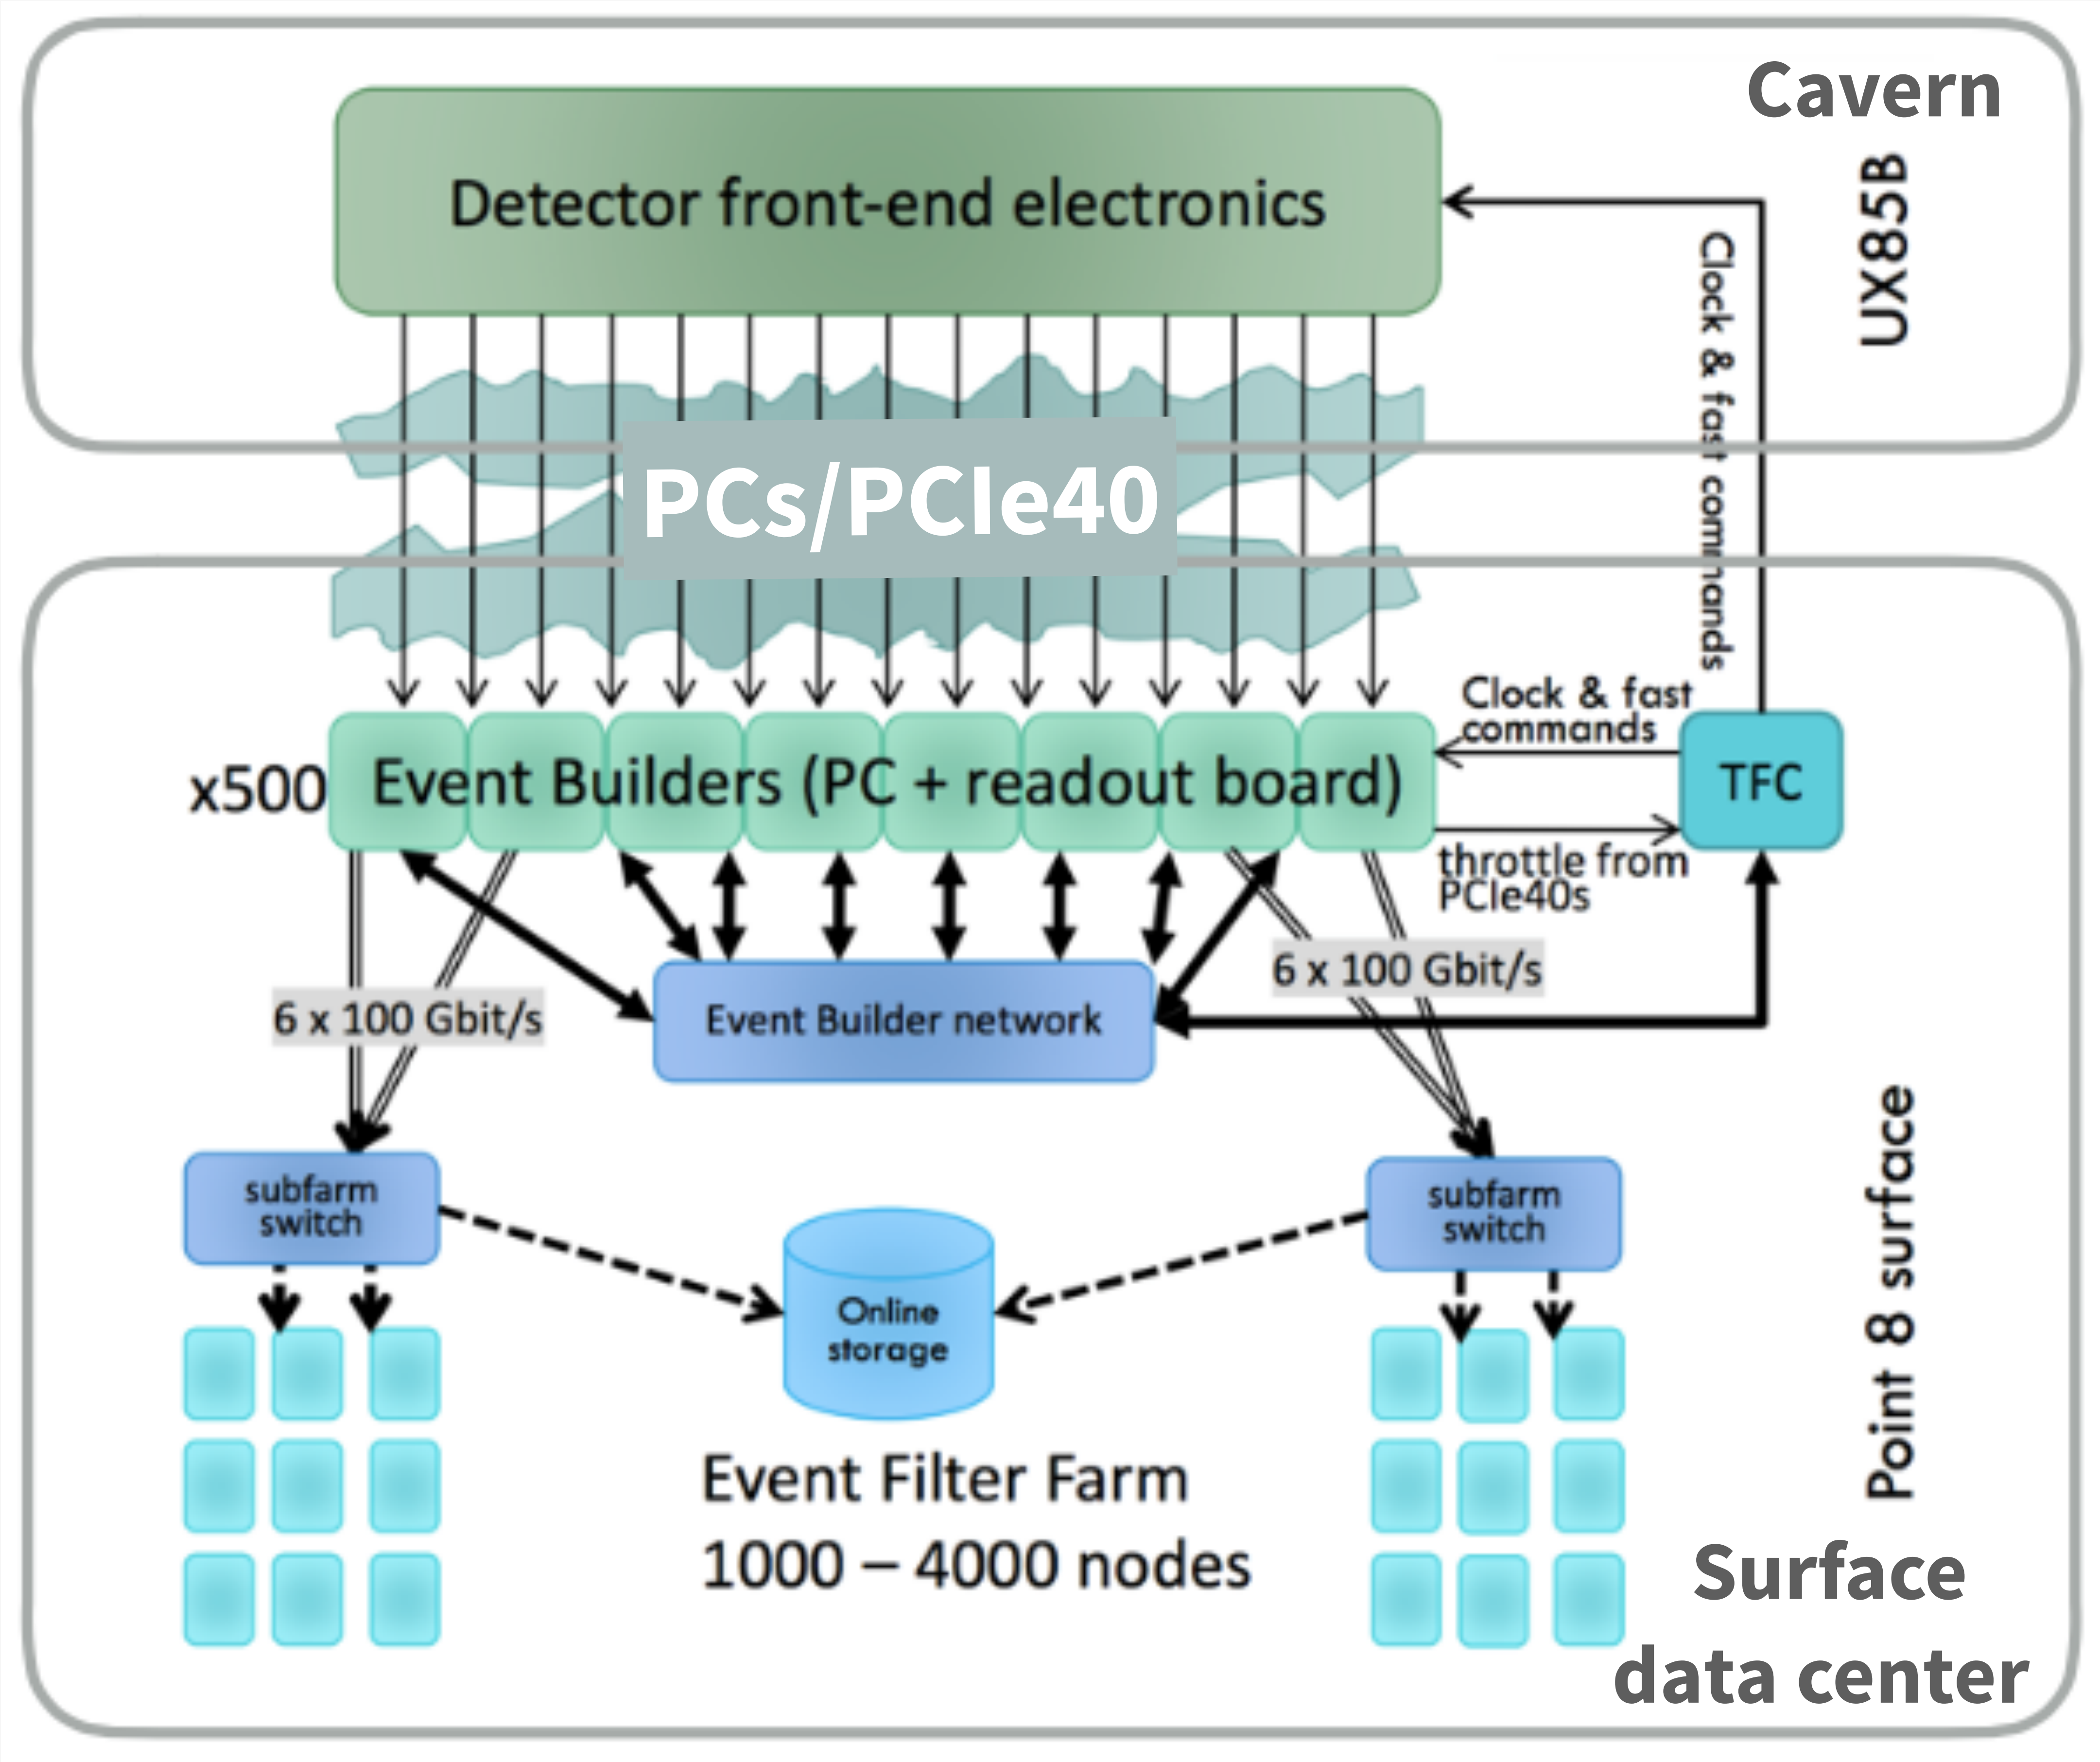
Data reduction before EB

- custom readout FPGA-card (PCIe40)
- each sub detectors with its packing algorithm, i.e. zero-suppression and clustering

Readout: ~10,000 GBT links (4.8 Gb/s, rad-hard)

DataFlow: Merged EB and HLT

- reduced network complexity
- scalable up to 400 x 100Gbps links



ALICE

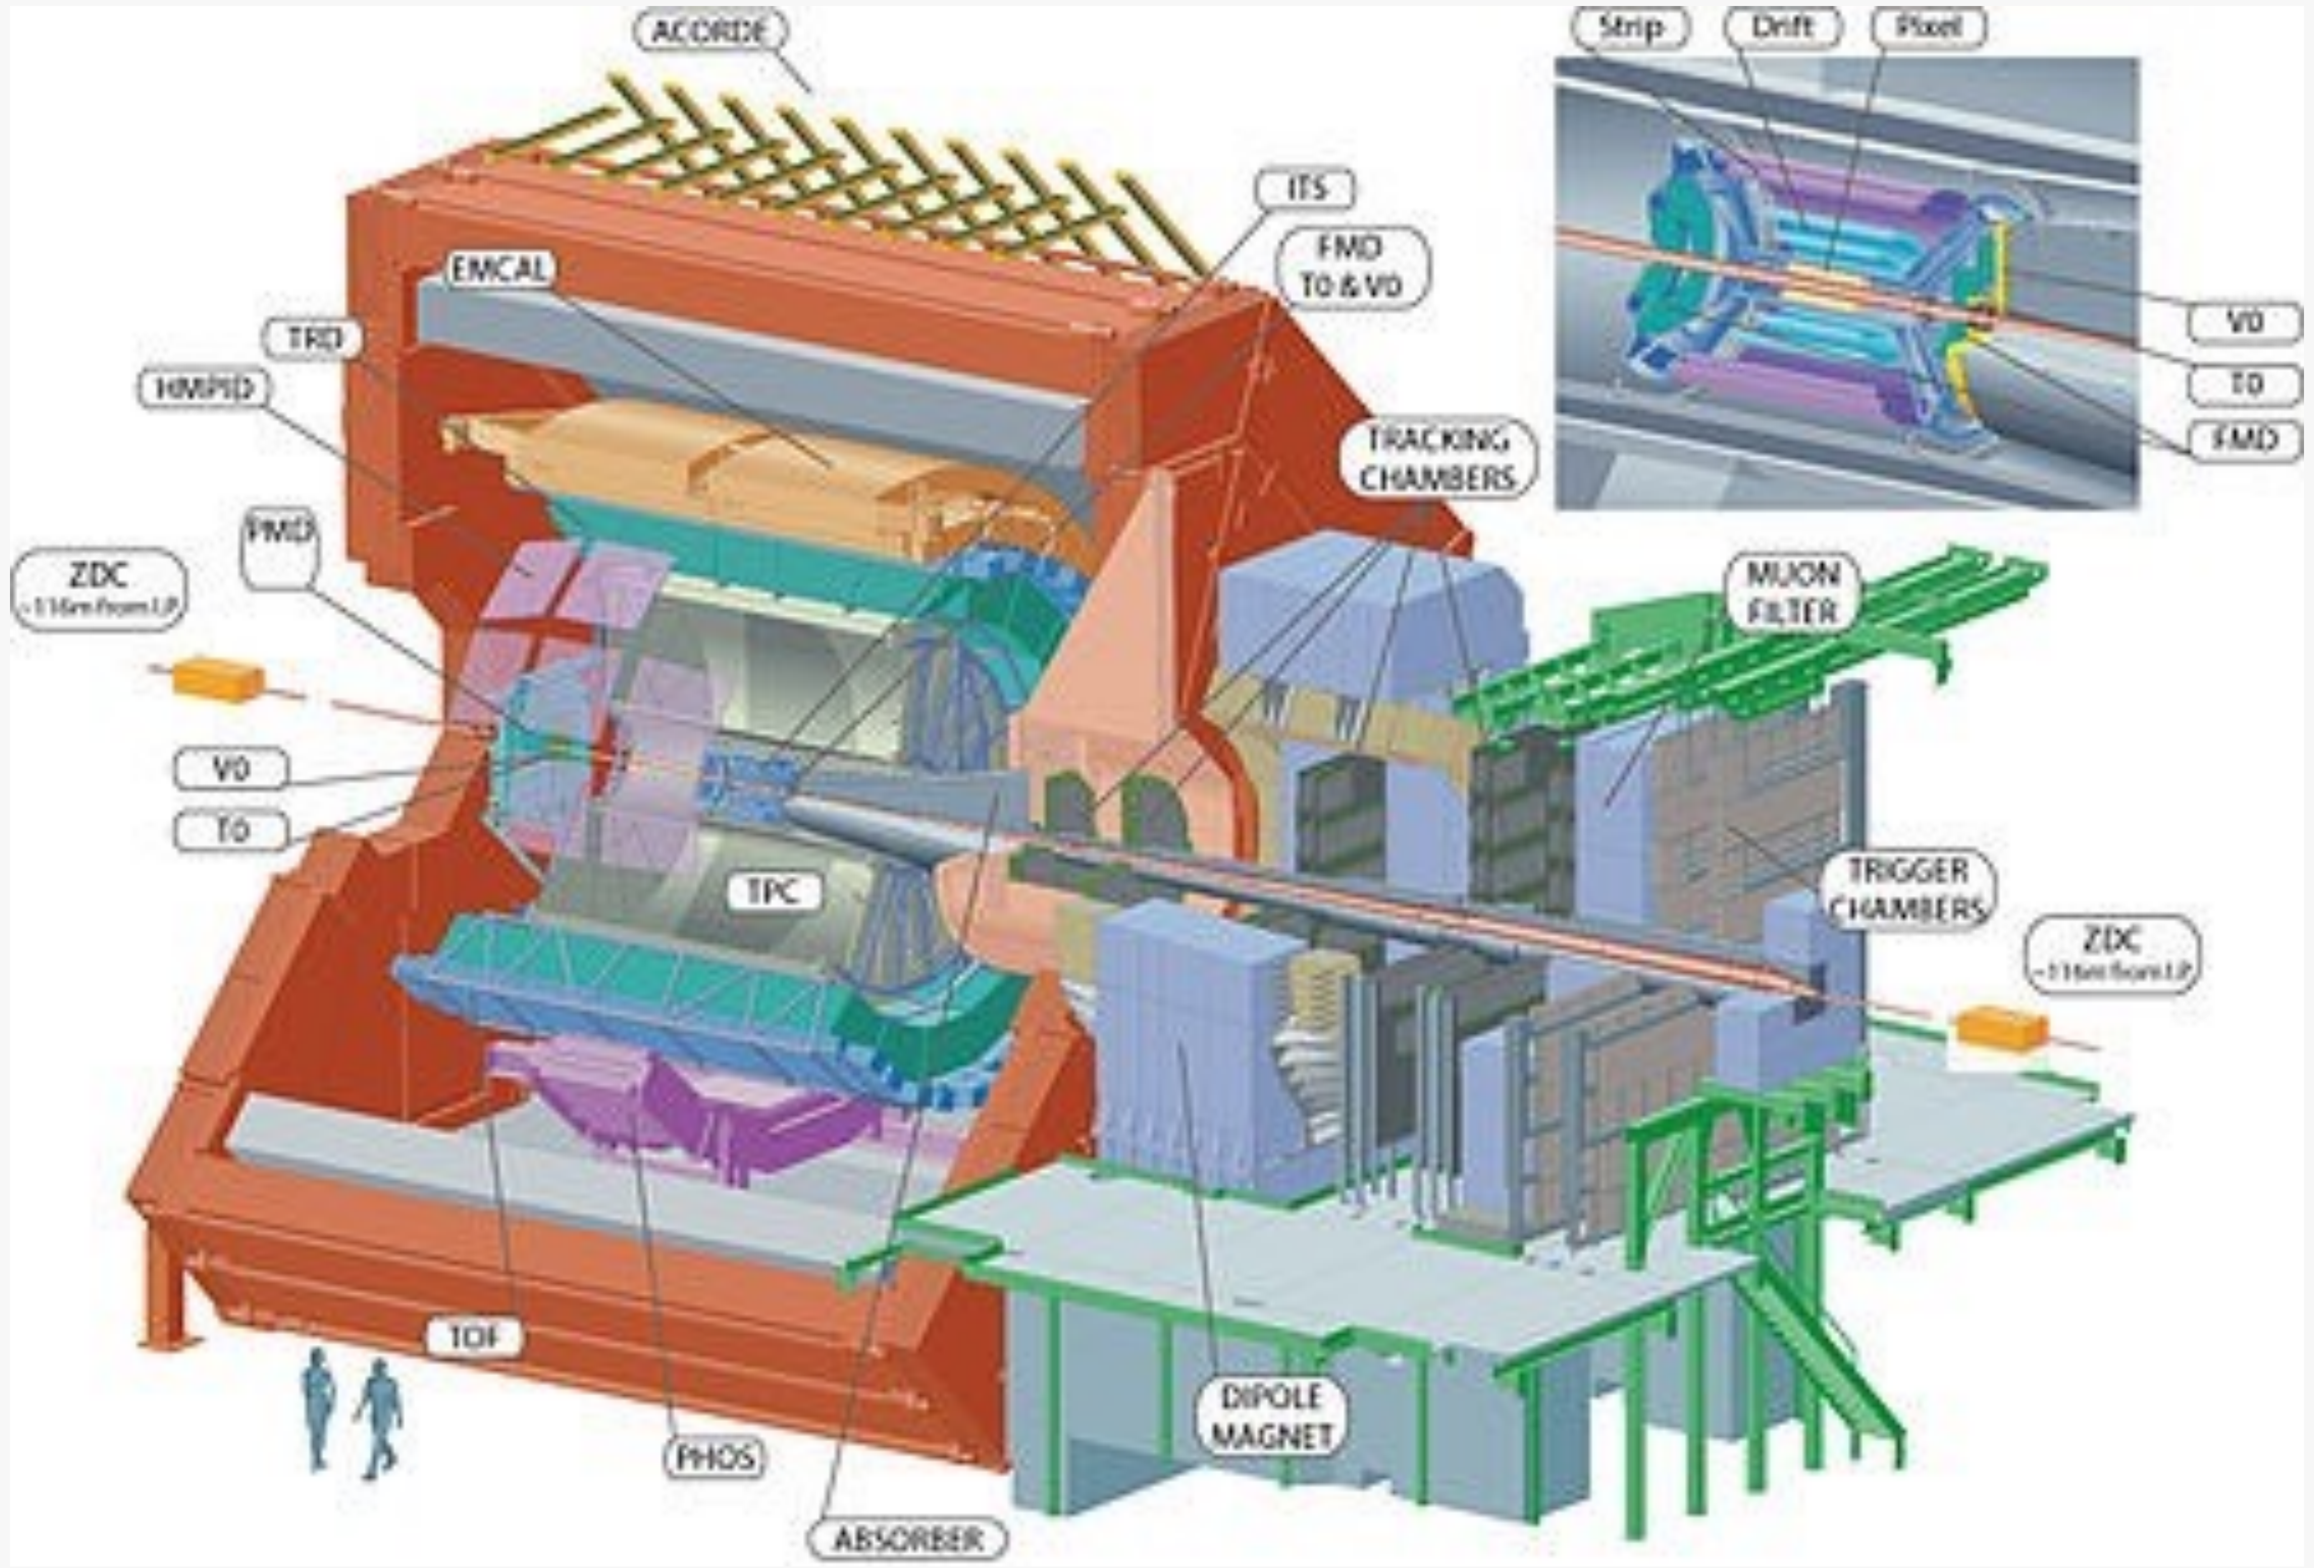
19 different detectors

- with high-granularity ant timing information
- Time Projection Chamber (TPC):

  very high occupancy, slow response

Large event size (> 40MB)

- TPC producing 90% of data



Challenges for the TDAQ design:

- detector readout: up to ~50 GB/s
- low readout rate: max 8 kHz
- storage: 1.2 TB/s (Pb-Pb)

ALICE TDAQ architecture

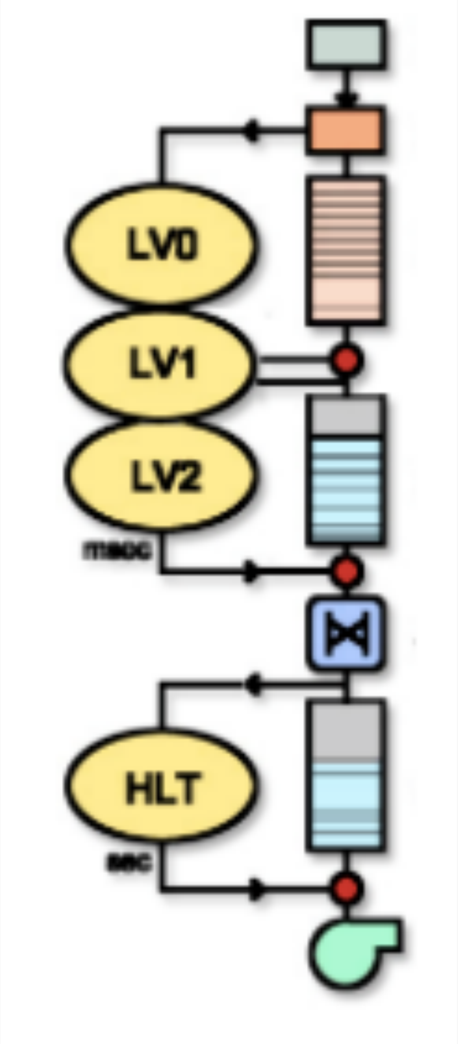
Hardware

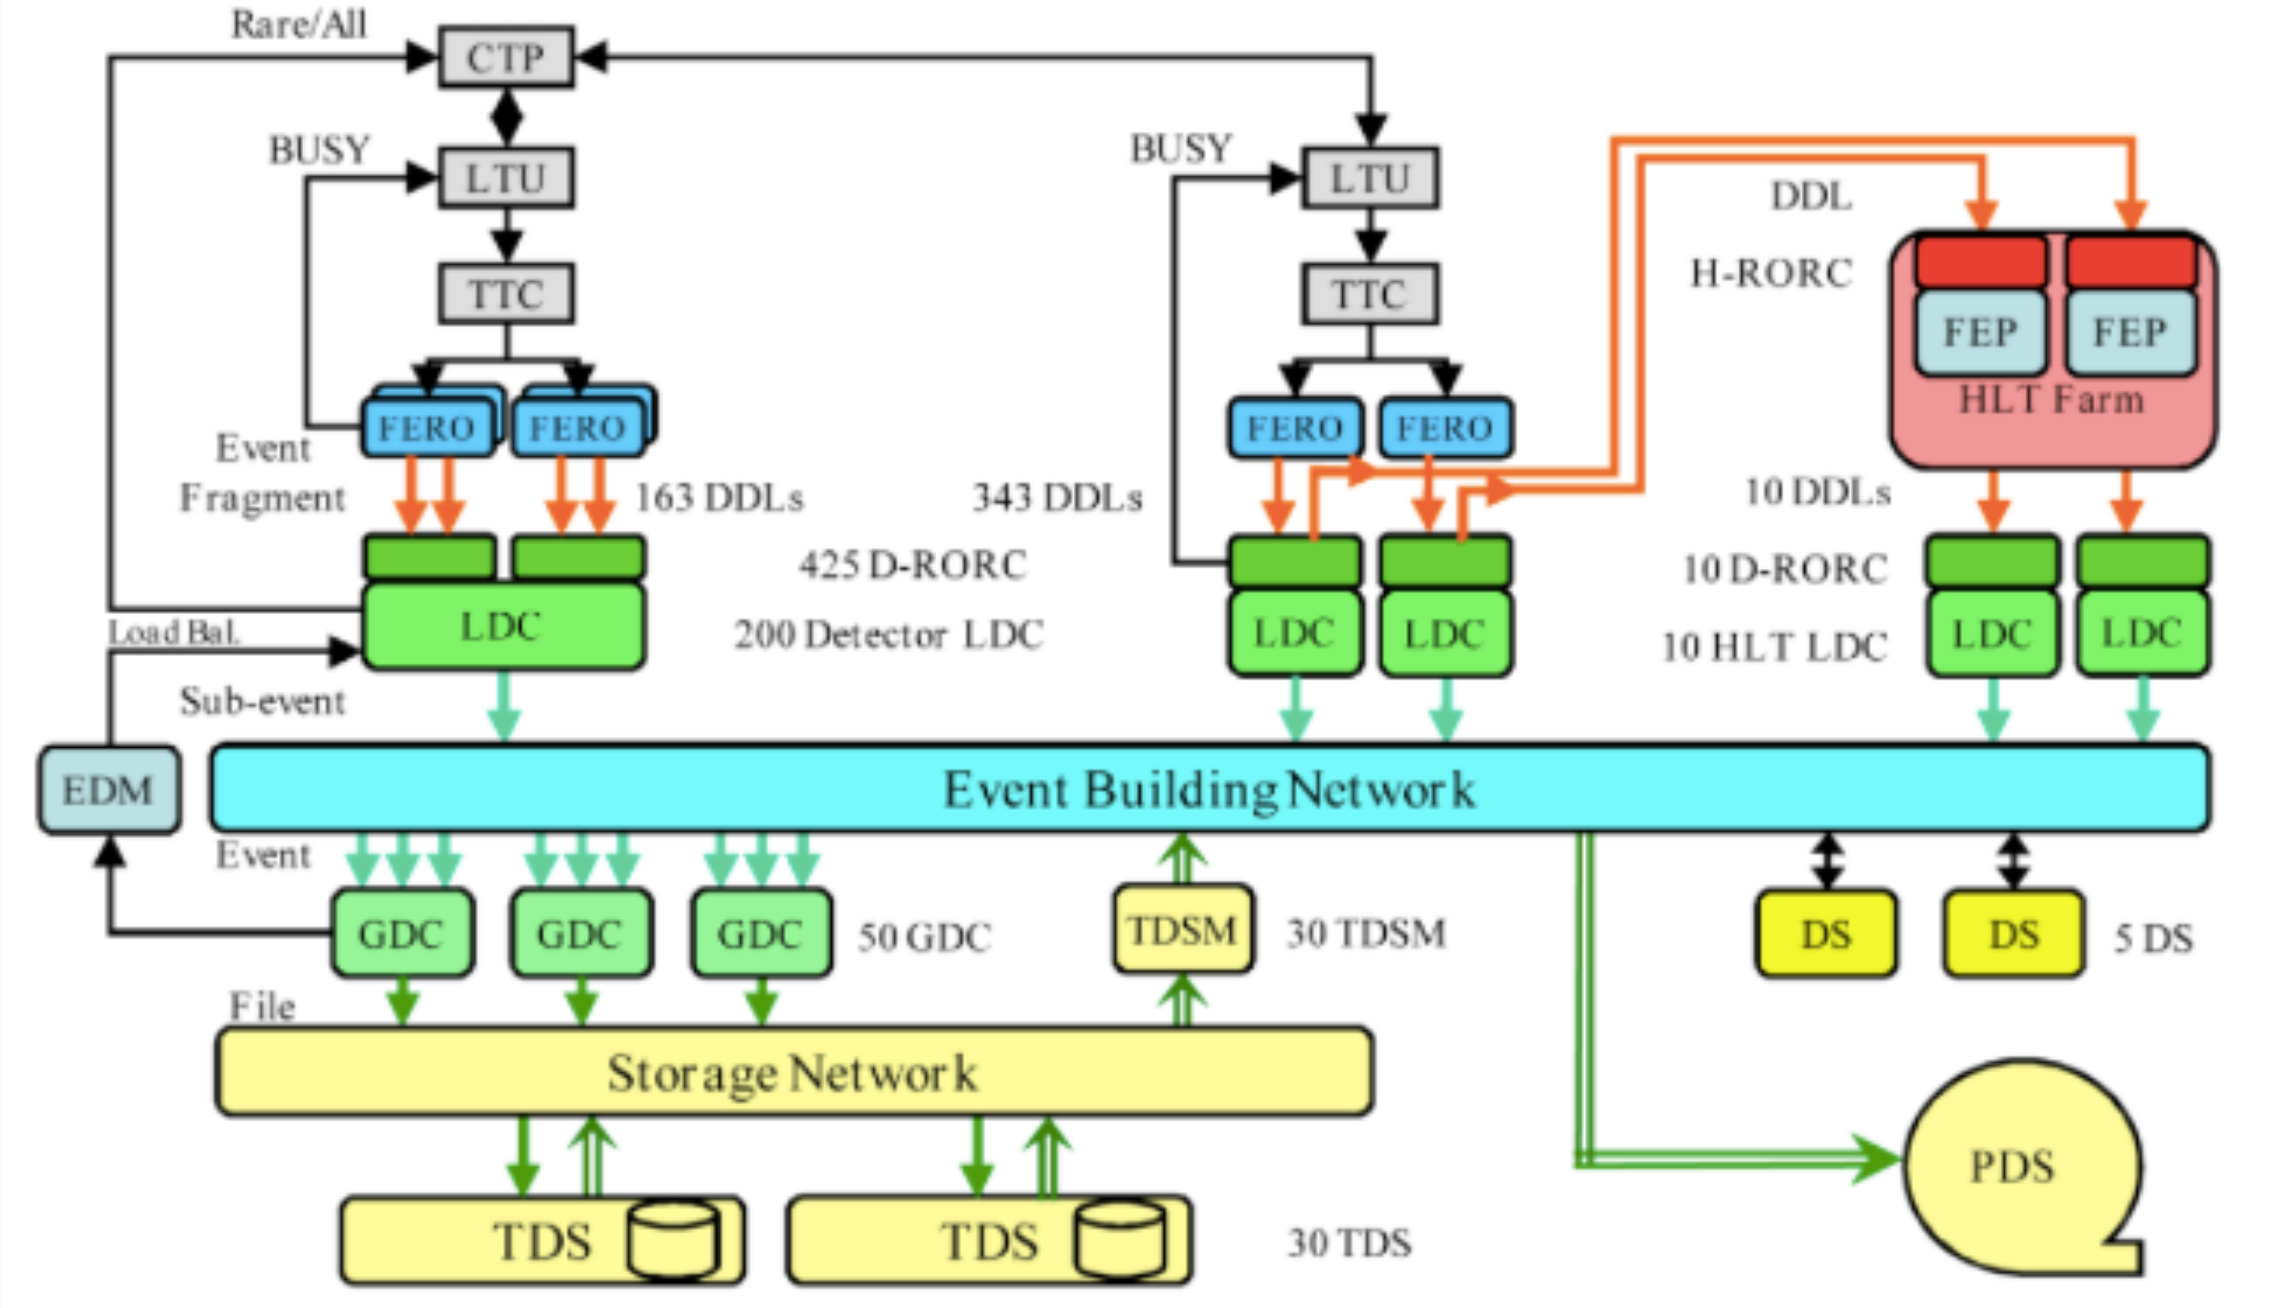
1.2µs

6.5µs

8.8µs

Software





Trigger

- 3 hardware levels
- 1 software

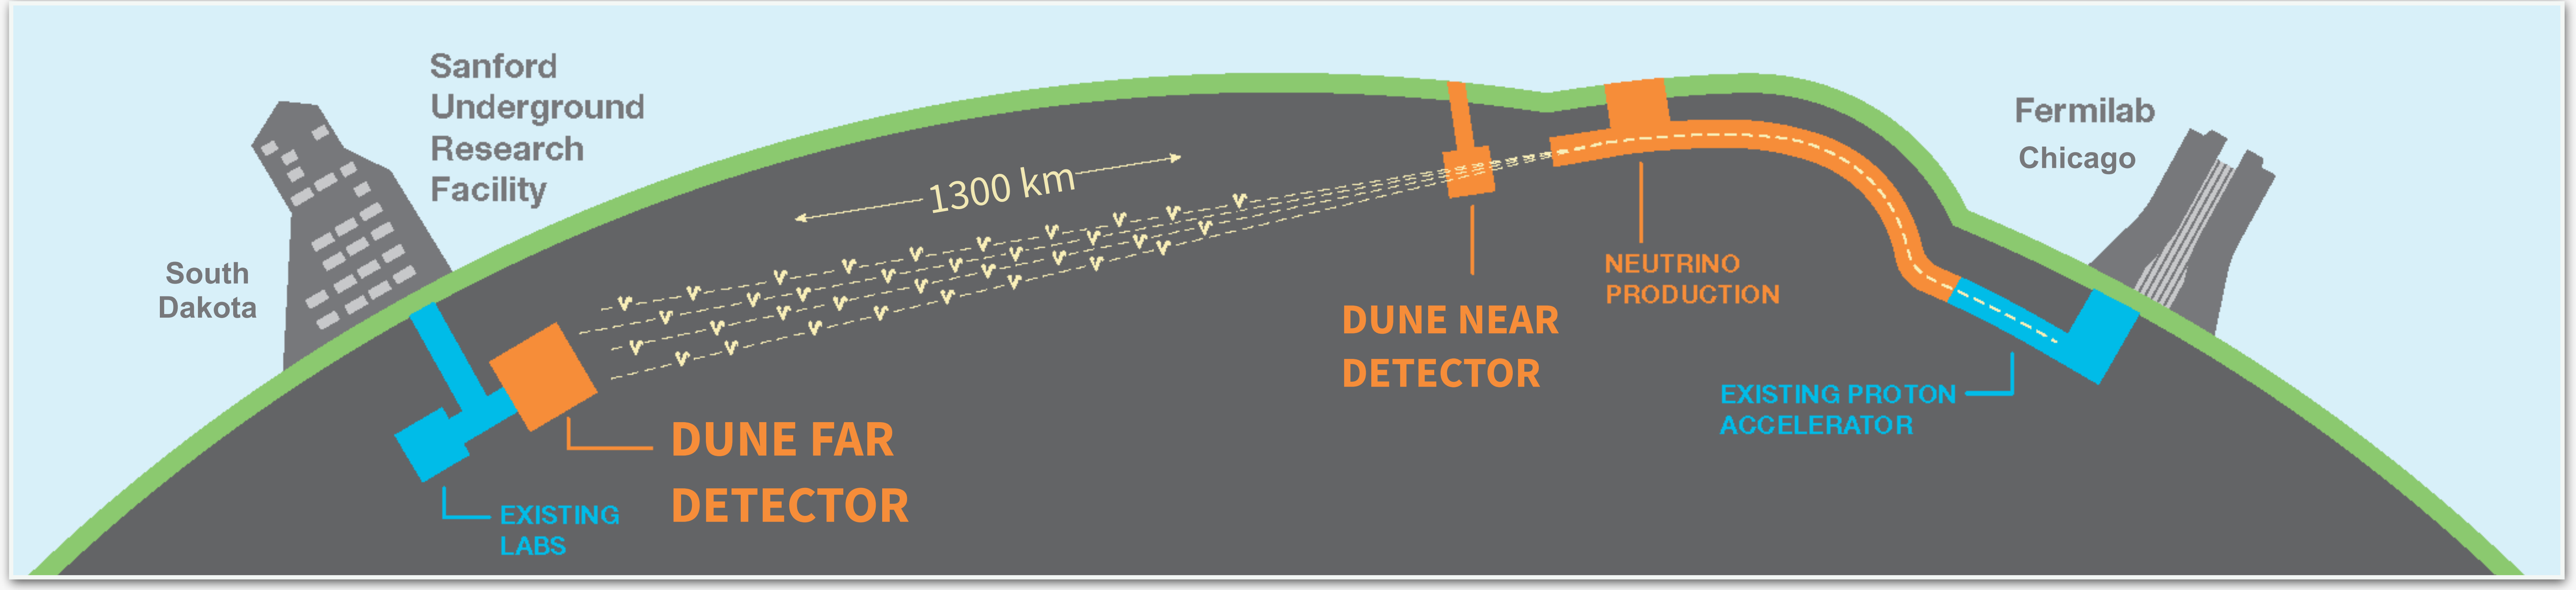
Detector readout (~20 GB/s) with point-to-point optical links

- ~ 400 DDL to RORC PCI cards (6 Gbps)
- data fragments directly into PC memory of LDCs, at 200 MB/s (via DMA)

Dataflow with local LDC and global GDC data concentrators (for Event Building)

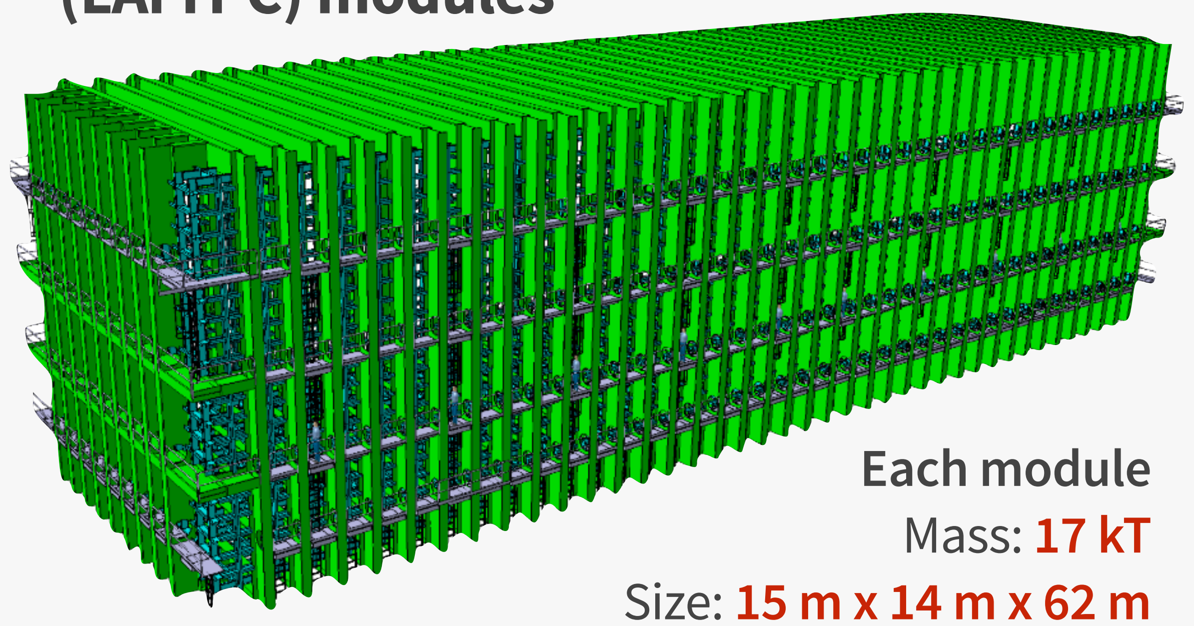
- HLT as any other sub-detector in DAQ

The Deep Underground Neutrino Experiment - DUNE



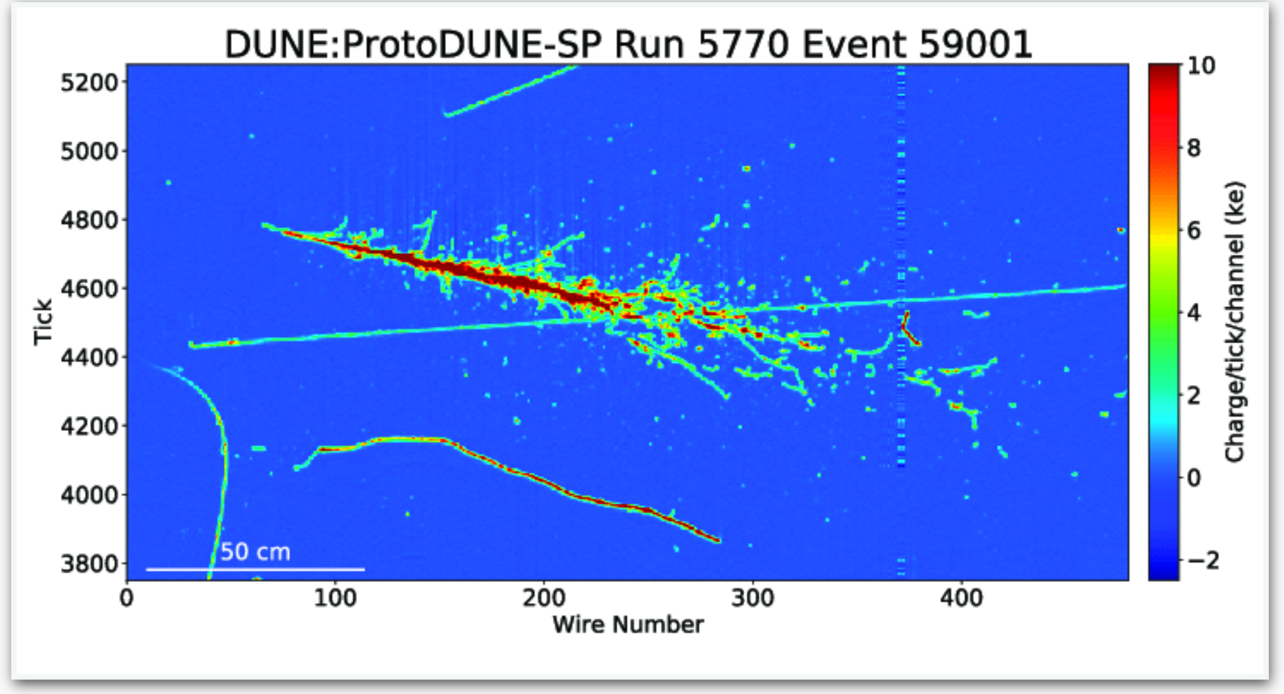
TDAQ: no quick access and no large host lab in the vicinity!

4 Liquid Argon Time Projection Chamber (LArTPC) modules



Each module
Mass: **17 kT**
Size: **15 m x 14 m x 62 m**
Operational temperature: **-186 °C**

High-resolution imaging detector



spatial resolution: **5mm**

Leading edge, world class neutrino experiment with high profile physics programme

- Nature of neutrinos, supernova collapse, proton decay searches

Gigantic Far Detector

- Huge target mass AND high resolution imaging

TDAQ: 4 independent instances, synchronized to a common clock, supporting different detector technologies

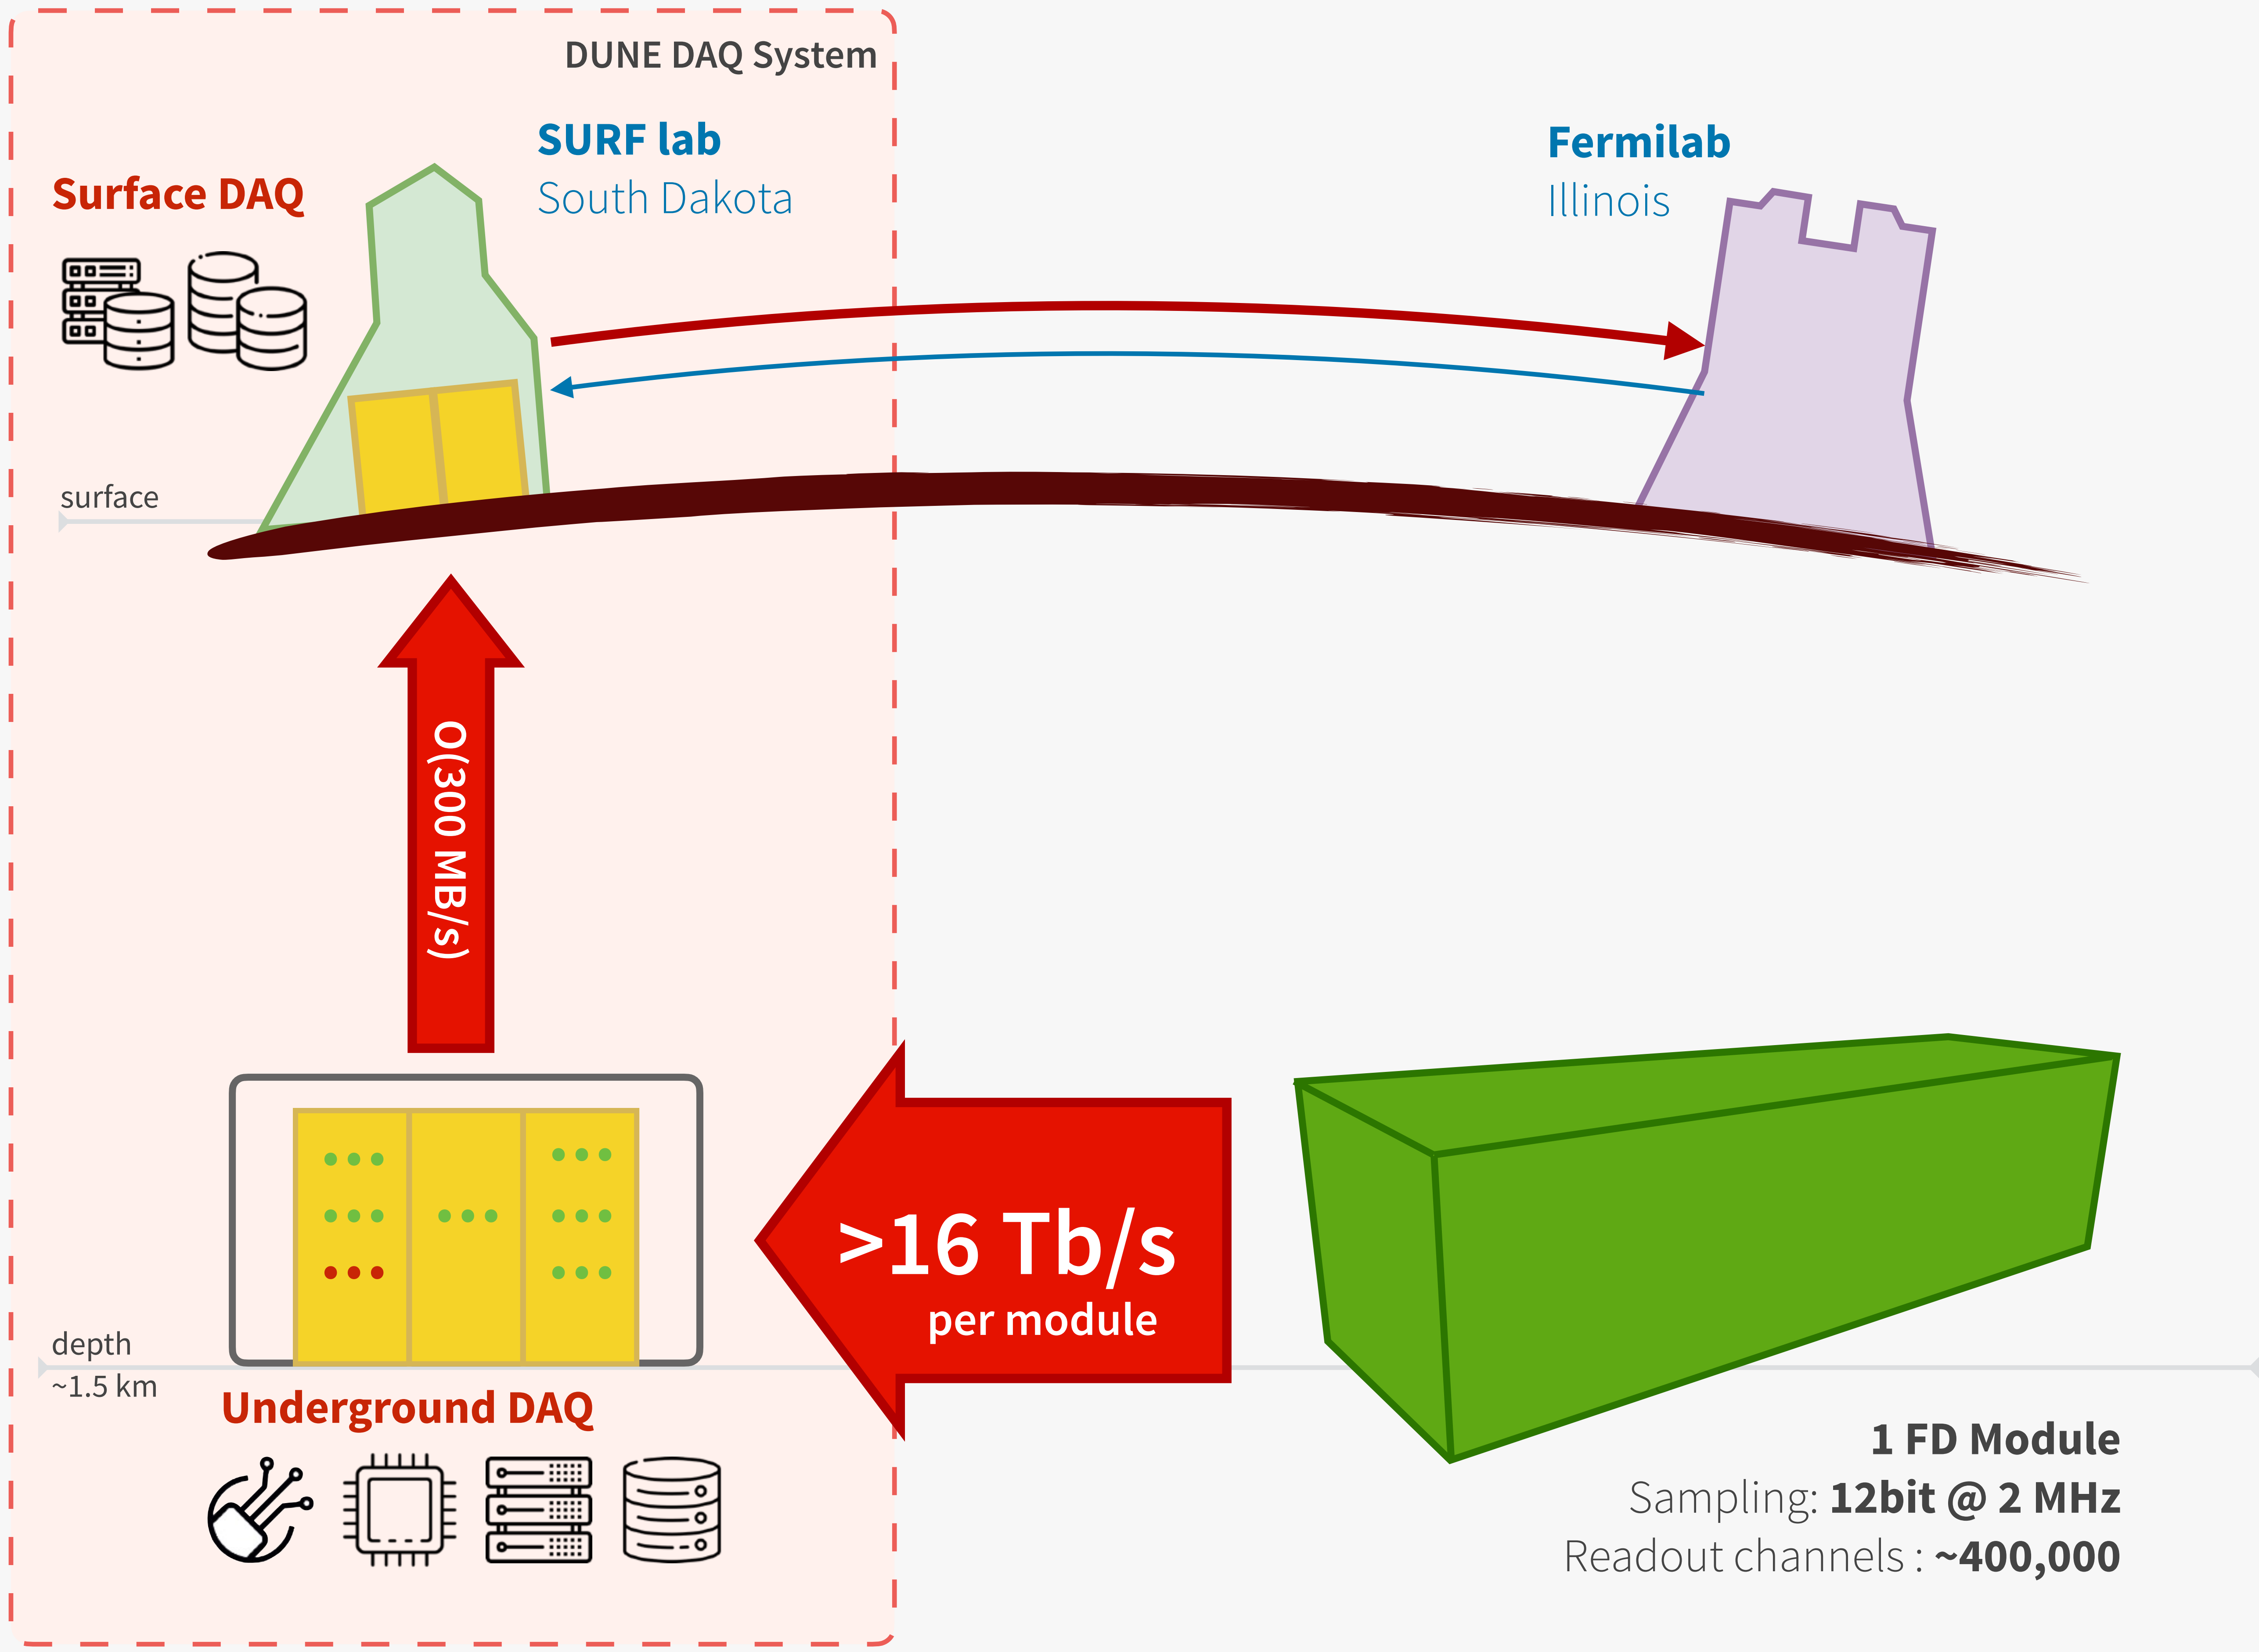
The DUNE Data AcQuisition System - DAQ

DUNE DAQ System

- Collects large amount of **streaming** data from detectors
- Selects only interesting interactions
- Buffers the **full data stream** for ~100s for supernova physics
- Deliver selected interactions to permanent storage

Unique challenges

- **High data rate, high uptime**
- **Remote experimental site**
- **Deep underground in an active mine**



Summary

This lecture is just an introduction about data acquisition

- DAQ (& Trigger) is a complex and fascinating topic, combining very different expertise
- More details on **Trigger** and **FPGAs** in the following lectures

Covered the principles of a simple data acquisition system

- Basic elements: trigger, derandomiser, FIFO, busy logic
- Scaling to multi-channel, multi-layer systems
- How data is transported
  - Bus versus network

A (very) brief overview of LHC experiments + DUNE DAQ systems

- Similar architectures, different optimisations driven by detector requirements
