

# 15th International Conference on Muon Spin Rotation, Relaxation and Resonance

Contribution ID: 222 Contribution code: P-TUE-22

Type: Poster

## The interaction between positive muons and multiple quadrupolar nuclei

*Tuesday, 30 August 2022 18:40 (20 minutes)*

A positively charged muon implanted in copper sits at an octahedral interstitial site and experiences a magnetic dipolar coupling with six nearest-neighbour quadrupolar  $I = 3/2$  copper nuclei [1]. The resulting avoided level crossing resonance observed as a function of magnetic field [2] provides a means of studying these interactions and understanding the effect of the electric-field gradient due to the muon experienced by the quadrupolar nuclei. The effect is usually modelled by considering the interaction between the positive muon and a single copper nucleus, but the other five copper nuclei are equally important. By solving the problem in the full  $2(2I + 1)^6 = 8192$ -dimensional Hilbert space, we demonstrate the effect of these additional interactions.
