Single-Particle Linear Dynamics

Problem Set 4

A. Wolski

April 2022

1. Write down the 4×4 submatrix for the transverse components of the transfer matrix for a quadrupole of normalised field strength k_1 and length L. Find the form of this 4×4 matrix in the limit $L \to 0$, where:

$$\lim_{L \to 0} k_1 L = K \tag{1}$$

and K is a finite constant. (This is the *thin lens* approximation: K is the *integrated strength* of the quadrupole).

2. A beamline consists of a thin quadrupole of integrated strength K, a drift of length $1/\sqrt{2}K$, a thin quadrupole of integrated strength $-2K$, a second drift of same length as the first, and a final thin quadrupole of the same integrated strength as the first quadrupole. The beamline is illustrated (schematically) below.

   (a) By multiplying 2×2 submatrices for the horizontal component of the motion in each of the elements along the beamline, find the 2×2 transfer matrix for the horizontal motion in the entire beamline.

   (b) Evaluate the 2×2 transfer matrix for the horizontal motion in the beamline in the case:

$$K = 1 + \sqrt{2} \tag{2}$$

   (c) Now consider a beamline consisting of the shorter beamline shown in Fig. **??** repeated an infinite number of times. Show that horizontal motion of a particle moving along the infinite beamline must be stable and periodic. What is the period of the motion? Without any additional algebra, describe in general terms the vertical motion of a particle moving along the infinite beamline.
